LECTURES

ON THE

EXPERIMENTAL INVESTIGATION OF THE ACTION OF MEDICINES.

By T. LAUDER BRUNTON, M.D., F.R.S.,

Casualty Physician and Lecturer on Materia Medica at St. Bartholomew's Hospital; etc.

V.—RESPIRATION.

Respiration in Unicellular Organisms; in the Cells composing higher Organisms.—Distinction between Respiration in an Amœba and a Fixed Cell.—Internal Respiration.—External Respiration.—Internal Respiration may be diminished or arrested by Diminution or Arrest of the Circulation generally or locally.—Pathology of Fatty Degeneration, by lessening or destroying the power of Hæmoglobin to act as an Oxygen-carrier. (a) Action of Carbonic Oxide; (b) Action of Nitrites; Action of Phosphorus.—Examination of the effect of Drugs on Hæmoglobin.—Colour.—Spectrum-reducing Agents.—Absorption of Oxygen.—Action of Carbonic Oxide.—Oxygenising Power of Blood.—Formation of Acid in Blood.—External Respiration.—Respiratory Movements.—Respiratory Nervous Centre; Excitants to this Centre.—Venosity of Blood.—Dyspœa.—Apnœa: two opposite meanings of this term.—Effect of Temperature on this Centre.—Effect of Drugs: Tartar Emetic, Chloral, Opium.

THERE is a great deal of truth in the oft-repeated comparison between an animal body and a steam-engine. In both, the motion which is their characteristic function is kept up by combustion, and for combustion there is necessary a free supply of fuel and a free supply of oxygen. Simple organisms, such as the amœba, which consists of a single cell or minute mass of protoplasm only, derive their oxygen, as well as their nutriment, from the fluid in which they swim, and the individual cells which compose the tissues of the higher animals are nourished in much the same way. As Bernard strikingly puts it, "we do not live in air" any more than a number of amœbæ swimming about in a glass of water live in air. The cells of which our bodies are composed live, like the amœba, in a fluid—the intercellular fluid or lymph in which they are bathed; and our skin may be compared to the glass in which the amœbæ and the water in which they swim are contained. There is, however, a very great difference between the amœba and the cells composing the bodies of the higher animals, for it can swim about freely, whereas they are for the most part fixed. The amœba can thus obtain fresh supplies of nutriment and oxygen by moving through the water in which it lives, while in higher organisms the fluid moves over the cells. This fluid, or lymph, is the liquor sanguinis, which passes out of the capillaries and supplies all the tissues with nutriment and oxygen, at the same time that it removes from the system carbonic acid and the products of tissue-waste.

The interchange of oxygen and carbonic acid between the tissues and the blood is termed *internal respiration*.

But this interchange would soon remove all the oxygen from the blood and load it with carbonic acid, unless it had some means of absorbing oxygen and giving off carbonic acid to the atmosphere. This is effected in the lungs, and the interchange of gases between the blood and external air is termed *external respiration*.

The blood, therefore, acts as an oxygen-carrier between the blood and the tissues. A certain amount of the oxygen taken up by the blood is simply dissolved in it; but the amount of this is not sufficient to supply the wants of the tissues, and the greater part of the oxygen which they require is carried to them by means of the hæmoglobin, or colour-

ing matter of the blood. This substance forms a loose compound with oxygen in the lungs, and gives it off to the tissues when it reaches the capillaries, and on again passing through the lungs it takes up a fresh supply. The carbonic acid which is formed in the tissues by their oxidation is taken up by the blood in the capillaries and given off in the lungs; but it seems to be carried from the tissues to the lungs, not by the hæmoglobin, but by some one or other of the salts in the blood. Both internal and external respiration are essential for the maintenance of life, and it may be destroyed by putting a stop to either one or other of them.

1. Internal respiration may be completely stopped by preventing supplies of fresh blood from reaching the tissues. The stoppage may be general or local. General stoppage of internal respiration is produced by arresting the circulation in the whole body, by stopping the action of the heart, or obstructing the flow of blood through the large vascular trunks which are connected with it. Internal respiration may be arrested locally in any part of the body by compressing or tying either its arteries or veins. Thus, if the arteries going to the head be tied, so that no fresh blood can reach it, or the veins coming from it be ligatured, so that the deoxygenated blood cannot leave it, the blood which is present in the capillaries of the brain loses all its oxygen and becomes charged with carbonic acid. The nervous centres are thus effectually suffocated, although the lungs may be working vigorously, and the blood in the rest of the body may be richly arterialised. That the loss of function which follows stoppage of circulation in a part is due to the want of the oxygen carried to it by the blood, rather than to the want of nutriment, is well shown by the experiment of Kronecker, who found that contractility could be restored to the excised gastrocnemius muscle of a frog, after exhaustion by repeated contractions, by passing through its vessels a solution of permanganate of potash, which supplied oxygen to the interior of the muscle, but conveyed to it no nutrient matter.

When the circulation is diminished but not completely arrested, as, for example, by weakening the heart, or by contracting without obliterating the lumen of the blood-vessels, or when the oxidising power of the blood is impaired, internal respiration will be diminished, but not stopped.

The tissues, or at any rate the albuminous tissues, in all probability do not undergo combustion directly; *i.e.*, the albumen does not combine at once with oxygen. It is first split up by the action of a ferment into nitrogenous substances, which, after being oxidised, form urea and non-nitrogenous substances, such as fat, and probably also glycogen. When internal respiration is imperfect, the nitrogenous substances may not be oxidised, and appear in the urine instead of being converted into urea. The non-nitrogenous substances may also continue unoxidised, and, instead of being converted into carbonic acid, remain in the tissues as fat, giving rise to fatty infiltration or fatty degeneration. This is seen in the heart when the size of the coronary arteries is diminished by atheroma. The supply of blood being insufficient to keep up perfect combustion in the muscular fibres, the non-nitrogenous products of decomposition accumulate and cause the heart to become fatty.

When there is little hæmoglobin in the blood, as in anæmia, internal respiration is diminished, and there may frequently be noticed a tendency to the deposit of fat in anæmic girls. The peasantry in some parts of Germany are acquainted with this fact, and bleed their cows so as to induce an artificial anæmia whenever they wish to fatten them.

2. Internal respiration may be arrested by the action of substances which deprive hæmoglobin of its power to take up and give off oxygen easily, and thus render it useless as an oxygen-carrier. *a.* Certain gases—for example, carbonic oxide and nitric oxide—do this by driving out the oxygen from its combination with hæmoglobin, and forming compounds with it themselves. These compounds resemble those with oxygen, but are more stable, and are not decomposed during the passage of the blood through the capillaries, nor by the action of reducing agents added to the blood, as oxyhæmoglobin is. *b.* The oxygen-carrying power of hæmoglobin has been shown by Dr. Arthur Gamgee to be also destroyed by nitrites, but in a different way. Instead of driving out the oxygen from its combination with hæmoglobin,

the nitrites combine with the oxyhæmoglobin, and as it were lock up the oxygen in it, so that the oxygen no longer separates from the hæmoglobin when the compound is placed in a vacuum, nor can it be driven out by the action of carbonic oxide. At the same time, the blood which has been acted on by nitrites is deprived of its power of absorbing any more oxygen. But, although the nitrites lock up the oxygen in oxyhæmoglobin so firmly that it cannot be driven out by carbonic oxide, they do not prevent its removal by reducing agents. These first break up the nitrite compound, and then deoxidise the hæmoglobin; and, when this is next exposed to air, it takes up oxygen in the normal way. On this account, the action of nitrites in impeding or arresting internal respiration is only transitory; for, when the blood on which they have acted once becomes deoxidised during its passage through the capillaries, it is restored to its normal condition. The action of carbonic oxide, on the contrary, is permanent, the blood with which it has combined remaining unaltered during its circulation either through the body or the lungs; and, if the greatest part of the hæmoglobin have been acted upon, life can only be saved by the transfusion of fresh blood into the vessels, although, in slighter cases, a fatal issue may be averted by the diligent use of artificial respiration. Internal respiration is also diminished by phosphorus; and the fatty degeneration produced by this substance has been shown by Voit and Bauer to be partly due to this action. It is not due to this alone, however, for the phosphorus has a double action: 1. It causes the albuminous tissues to split up more rapidly; 2. It lessens the combustion of the products of decomposition. The increased rapidity of albuminous decomposition causes more urea to appear in the urine; and, if the nitrogenous compounds be not sufficiently oxidised, leucin and tyrosine may appear instead of urea. Fat is also formed from albumen more rapidly, as well as more slowly oxidised, than in the normal condition.

In order to ascertain whether the hæmoglobin of the blood has been altered by the action of a drug: 1. If it be poisonous, examine the blood from the arteries and veins of an animal which has been poisoned by it, and note whether its colour is normal in both sets of vessels or not. 2. Dilute a portion of this blood with water, examine it with the spectroscope, and see what spectrum it presents. Shake it with air, and observe if the bands of oxyhæmoglobin alone are present, and if they are of their normal intensity and in their normal place. Take another portion of the diluted blood and add to it a deoxidising solution, such as sulphide of ammonium or Stokes's fluid,* and see if the spectrum of reduced hæmoglobin appears. 3. Take two portions of normal blood, or of a solution of hæmoglobin, and add to one of them the drug to be tested, or pass it through, if it be a gas. Note, as before, whether any change is produced in the colour or spectrum, or in its behaviour to oxygen or reducing agents. 4. Take two equal portions of diluted blood or solution of hæmoglobin in small test-tubes, shake them with air till they are thoroughly oxygenated, and add to one of them the drug to be tested. Then add to each an equal quantity of deoxidising solution. Let the test-tubes be full, and cork them so as to exclude the solutions from contact with air. Note the length of time which elapses before the spectrum of oxyhæmoglobin disappears and is replaced by that of reduced hæmoglobin in each. 5. Take two equal portions of normal blood, and act on one of them with the drug. Bring them into contact with equal portions of oxygen or air, and let them remain so for some time. Then ascertain how much oxygen has been absorbed and how much carbonic acid has been evolved by each, by seeing whether any alteration has taken place in the volume of the gas, and by analysing it in order to determine its composition. 6. Act on a portion of normal blood with the drug; arterialise it completely, and then determine the amount of each gas which it contains by extracting them by means of warmth and a vacuum, and analysing the mixture thus obtained. 7. Oxygenate a portion of blood thoroughly, act on it by the drug, and then ascertain whether the oxygen can be driven out by carbonic oxide. To describe the methods of gas-analysis would occupy more space than can be devoted to it here; and I must, therefore, refer to Bunsen's or Frankland's text-books on the subject, or to Sanderson's *Handbook for the Physiological Laboratory*; for an excellent example of the mode of ascertaining the action of a drug on the blood, to Dr. Gamgee's paper on the Action of Nitrites in the *Philosophical Transactions of the Royal Society* for 1858, p. 589-625; and to Dr. Harley's paper on the Action of Alkaloids, etc., in the *Transactions* for 1864, p. 687.

The object of adding the drug to the blood before arterialising, as in 6, and after arterialising, as in 7, is to discover whether it prevents the blood from taking up oxygen in the former experiment, or of giving it off in the latter. Normal blood has the power to produce ozone, or to

withdraw it from substances which contain it, and transfer it to others which are easily oxidised. Arterial respiration may be modified, and the process of oxidation diminished, by the action of certain substances which deprive blood of this power. The usual test for ozone is fresh tincture of guaiac (1 part guaiac to 6 of alcohol), which is oxidised by it with extreme rapidity. It shows the progress of the oxidising process with great distinctness by the blue colour which it assumes. A few drops of tincture of guaiac are put upon a piece of porous paper, allowed to become almost quite dry, and a drop of blood or solution of hæmoglobin is then placed on it. In a few minutes, the drop becomes surrounded by a blue ring from the formation of ozone and the oxidation of the guaiac in its neighbourhood. The formation of ozone is independent of the oxygen contained in the hæmoglobin; and carbonic oxide-hæmoglobin will produce it as well as oxyhæmoglobin, provided air be present. When the hæmoglobin itself contains oxygen in the form of oxyhæmoglobin, the presence of air is not necessary to the reaction. The oxidation of guaiac by means of blood alone is, however, not nearly so easily observed as when another substance containing ozone is added to it, such as peroxide of hydrogen or oil of turpentine which has been kept for some time. The hæmoglobin takes the ozone from these substances, and yields it up again to the guaiac.

The method adopted by Briz, in order to test the influence of drugs on this ozonising power of hæmoglobin, is to take a mixture of tincture of guaiac with a few drops of ozonised oil of turpentine, and divide it into two parts. A few drops of a solution of the drug to be tested is added to one of them, and a few drops of solution of hæmoglobin then dropped into both. If the drug increase the oxidising power of the hæmoglobin, the solution containing it will become blue more quickly than the other, but more slowly if the oxidising power be diminished.

Another process more simple than that of analysing the gases of the blood has been used by him and his scholars Zuntz and Schultz, in their observations on the effect of drugs on oxidation in the blood. This process is based on the fact, noticed by Zuntz, that, immediately after blood has been drawn from the body, an acid begins to form in it, so that its normal alkalinity goes on decreasing. The formation of acid is most abundant during the first few minutes after the blood has been drawn, and before coagulation has taken place, so that Zuntz considers it a vital phenomenon; but it continues, though in a less degree, till putrefaction commences. They take the rapidity with which acid is formed as an index of the rapidity with which oxidation takes place in the blood; and, when they find that the addition of a drug to the blood has diminished the formation of acid in it, they consider that the drug has diminished oxidation in the same proportion. The following method is the one which they employ. Three equal portions of the same blood, of fifty cubic centimètres each, are measured out. The alkalinity of the first portion is then determined at once. To a second portion, the drug to be tested is added. The solution of the drug must be neutral; or, if it be acid, the amount of its acidity must be determined and allowed for in the final calculations. To the third portion, nothing is added. The second and third portions are then kept for one or two hours at a temperature of about 40 C. They are then allowed to cool, and the alkalinity of both portions is determined. If acid have been formed in either of these portions during this time, the alkalinity will of course be less than that of the first portion, and the amount of acid formed is estimated by the diminution which the alkalinity has undergone. The alkalinity is ascertained by noting what quantity of a standard solution of phosphoric acid must be added to the blood before it begins to give a red colour to blue litmus paper. But, if phosphoric acid were used alone, the red colouring matter of the blood would be apt to stain the litmus-paper, and it would be almost impossible to say when the reddening was due to it, and when to free acid. In order to prevent this, a quantity of chloride of sodium is added to the acid. The salt prevents the corpuscles from being dissolved, and the hæmoglobin from disturbing the reaction. The acid and salt are gradually added to the blood, and the reaction tested from time to time by putting a drop of the blood on a piece of fine satin-paper coloured with litmus. The paper should be first moistened with a tolerably strong salt solution, the drop of blood allowed to remain on it for a few seconds, and then wiped off with blotting-paper. The point of saturation is held by Schulte, who has also employed this process, to be reached whenever the blue litmus-paper becomes distinctly reddened, even though the red colour should disappear again immediately. This transient reddening is due to carbonic acid; and Schulte prefers it to the first permanent reddening, because it can be more easily observed. This does not give the absolute amount of alkalinity; but all that is wanted is the comparative alkalinity of the three portions, and this is got accurately enough if they be all treated in the same manner as regards temperature, shaking, etc. In this way, Zuntz, Scharrenbreich, and Schulte, find that quinine lessens oxidation in the

* Stokes's fluid consists of a solution of protosulphate of iron, to which is added a sufficient quantity of tartaric acid to prevent precipitation, and then as much ammonia as will render it decidedly alkaline.

blood, and Binz finds that it does the same in a solution of hæmoglobin.

External respiration, or the interchange of gases between the blood and the atmosphere, takes place whenever they come into sufficiently close relation with one another, as they do in the capillaries of the skin, intestinal canal, or lungs. In the frog, respiration is carried on by the skin to such an extent, that it can live for a considerable time after the lungs have been excised; but in mammalia respiration is carried on almost entirely by these organs, and any interference with their function quickly puts an end to the life of the animal. In order that the blood which circulates through the body may get rid of its carbonic acid and take up oxygen sufficient for the wants of the tissues, fresh portions of it must constantly be brought into contact with the air, and therefore it must constantly circulate through the pulmonary capillaries. But the air in the lungs would soon become saturated with carbonic acid and deprived of its oxygen by the blood which comes into contact with it, and all farther diffusion would be arrested, unless it also were constantly renewed. This is effected by the respiratory movements. These consist in the alternate enlargement and diminution of the thoracic cavity, after the fashion of a pair of bellows, by the motion of its walls and of the diaphragm. These movements are kept up in a rhythmical manner by a nervous centre, situated in the medulla oblongata and upper part of the spinal cord, which sends off periodic motor impulses to the diaphragm and inspiratory muscles. When the breathing is quiet, expiration is usually a passive act performed by the elasticity of the lungs and ribs, and by the weight of the thoracic walls. But when it becomes excited, active expiratory muscles are brought into action, and they receive their motor impulses from the respiratory centre alternately with those of inspiration. It is probable, though not certain, that the respiratory centre is not a mere reflex apparatus, which simply transmits impressions which it receives from sensory nerves to motor ones; for its activity continues, although its connections with sensory nerves be almost entirely destroyed. The periodic impulses which it imparts to the motor nerves of the respiratory muscles are not due to its being periodically excited by impressions from afferent nerves, but to its being constantly excited by the venosity of the blood circulating in it; while some resistance within itself prevents the excitation from being constantly transmitted to motor nerves, and only allows it to be so at periodical intervals.

The venosity of the blood consists in the absence of oxygen and the presence of carbonic acid, and it is not certain whether or not both of these act as excitants to the respiratory centre; but it seems not improbable that the presence of carbonic acid is the excitant, while the amount of oxygen simply alters the excitability of the centre. According to this view, when there is much oxygen in the blood, the excitability of the centre will be slight, and little affected by any irritant applied to it, whether this be carbonic acid or anything else. When the amount of oxygen in the blood is small, the centre will be very excitable and easily affected by any irritant. In venous blood, there is both little oxygen and much carbonic acid, so the centre is both rendered more sensitive, and is more strongly excited by the acid. The more venous the blood, the greater is the excitation of the respiratory centre, and the more active the respiratory movements. When other interfering circumstances are excluded, it would appear that greater excitement of the respiratory centre causes the respirations to become quicker, and, at the same time, deeper. This excited respiration is termed dyspnoea, and it occurs when the blood becomes venous in the respiratory centre. As the venosity increases, the ordinary muscles of respiration are no longer employed alone, but the expiratory and accessory muscles are called into play; and, lastly, all the muscles of the body are affected by clonic convulsive movements, called asphyxial convulsions.

When the blood which circulates in the respiratory centre is not at all venous but is perfectly arterialised, as it is when artificial respiration is vigorously performed, the centre is both rendered less sensitive, and the irritant, viz., the carbonic acid, is at the same time diminished or removed, the centre is not excited at all, and respiratory movements cease.

This condition, in which no desire for respiration is felt, and respiratory movements cease, is termed "apnoea" by German writers, and it must be carefully distinguished from the "apnoea" of English authors, which is simply extremely great dyspnoea; so great, that the blood is hardly aerated at all.

The activity of the respiratory movements and the amount of air respired in a given time, depend on the degree of excitement of the respiratory centre. As we have just seen, this excitement depends on two factors; 1. The excitability of the centre; and 2. The amount of irritation applied to it. In general, the venosity of the blood determines both factors, and it is not the venosity of the blood in the general circulation which does this, but only of that blood which courses

through the vessels of the medulla. This was shown by Hering, who passed a stream of arterialised blood through the vessels of the head while venous blood was circulating in those of the body. The respiratory movements then ceased exactly in the same way as if the whole blood in the body had been perfectly oxygenated. When he reversed these conditions, and passed arterialised blood through the body and venous blood through the head, asphyxial convulsions took place. This shows that the degree of activity of the respiratory centre in the medulla oblongata depends on the greater or less venosity of the blood circulating through it, and not on an irritating action exerted by venous blood on the ends of afferent nerves in the lungs, or other viscera.

The excitability of the respiratory centre may be greatly modified; 1. By the temperature of blood in it; 2. By the action of drugs upon it. When the blood becomes warmer, the excitability of the respiratory centre is greatly increased; the movements of respiration become much more vigorous, and it is no longer possible, by the most active artificial respiration, to produce a state of apnoea. Certain drugs, as tartar emetic, or apomorphia, when injected into the veins, also prevent the production of apnoea, but whether they do so by increasing the excitability of the centre, or by acting as irritants to it, is uncertain.

Other drugs, such as chloral, greatly diminish the excitability of the respiratory centre, so that the respirations become fewer, notwithstanding the increase of carbonic acid in the blood to which their diminution gives rise, and if the dose be large they may stop altogether. Apnoea may also be produced by means of artificial respiration with great ease after their administration, and it may last so long, that one is sometimes inclined to think that the animal is not going to breathe again at all.

FOUR CASES OF AFFECTION OF THE VERMIFORM APPENDAGE, WITH FATAL ISSUE.

By JOSEPH COATS, M.D.,

Lecturer on Pathology in Glasgow University, etc.

THESE cases are brought forward, not as offering any thing very new, but as illustrative of affections of the vermiform appendage, which are not very uncommon, but which, perhaps, are not sufficiently borne in mind in ordinary practice. The cases are, themselves, so illustrative, that their description involves almost all that need be said of the conditions involved.

CASE 1. Concretion in the Vermiform Appendage, consisting of inspissated Fæcal Matter. Inflammation of the Appendage, resulting in General Peritonitis.—This was the case of a middle-aged man, who, while apparently in perfect health, was attacked by symptoms resembling those of ileus, and which were at first supposed to be due to some internal incarceration of the bowel, or to strangulated hernia. A surgeon was consulted with a view to the latter question; the bowels were, however, freely moved by enemata, but without relief to the symptoms, and the patient died on the fourth day. On opening the abdomen, there were evidences of very acute recent peritonitis. The intestines were everywhere glued together with soft lymph, and the great omentum was adherent by its lower margin to the folds of intestine at the brim of the pelvis. The lymph was everywhere soft, but towards the right iliac region it was much softer than elsewhere, and there was here even fluid pus. On removing the lymph and pus, the vermiform appendage was found lying on the surface of the colon, in the form of a turgid black coiled up mass. It was much dilated, and most intensely congested, so as to have an almost gangrenous appearance. In the dilated appendage, which was congested through its entire thickness, a solid body about the size and shape of a cherry-stone was discovered. This foreign body was about the consistence of half-dry clay, and had a similar brownish yellow colour. On being cut into, this body, which, from its appearance, evidently consisted of dried fæcal matter, was seen to be stratified. The dilated portion of the appendage, in which the body was lying, did not appear to communicate with the peritoneal cavity—at least, no perforation could be discovered. The mucous membrane of the intestines was perfectly normal, and the calibre in no part obstructed.

In this case, it appears as if the small mass of inspissated fæcal matter had found its way into the vermiform appendage—possibly when of small size, as the stratification seems to indicate that it was of gradual growth, and the successive layers may have been added after its passage into the appendage. The mass acted as a foreign body, producing an intense inflammation of the appendage, which passed from its mucous to its serous surface, and thence to the general

serous surface of the abdomen. The peritoneal inflammation centred around the vermiform appendage, where alone there was a distinct formation of pus. It has been often said, that cherry-stones are apt to pass into the vermiform appendage and set up inflammation there. The foreign body, in the present case, resembled a cherry-stone both in shape and in size; and, if it had been just a little harder, might readily have been mistaken for one. It may be a matter of speculation how many of the reported cherry-stones were actually composed of inspissated faecal matter.

CASE II. Phthisis Pulmonalis. Ulceration of the Vermiform Appendage and Abscess around it. General Peritonitis.—Mary C., aged 16, was the subject of advanced phthisis pulmonalis, with cavities in both lungs. An acute attack supervened, which proved fatal. On opening the abdominal cavity, it was found to contain a considerable quantity of creamy pus, and the intestines were generally glued together by a very soft lymph, which was in great part breaking down into pus. A more defined abscess was discovered in the right iliac region, surrounding and lying between the folds of the vermiform appendage. The abscess, which was about the size of a walnut, contained glutinous pus, and matter of an exactly similar character distended the vermiform appendage, although it was doubtful whether any considerable communication existed between the two. The mucous membrane of the appendage was ulcerated; and, at its opening into the caecum, there was an ulcer with fungating prominent granulations. The ileum was the seat of numerous so-called tubercular ulcers, and there were also a few in the large intestine.

Here we have another case of general peritonitis resulting from disease of the vermiform appendage, but a very different disease from that in the first case. There was here ulceration of the appendage, similar to that often met with in the intestine, along with phthisis pulmonalis. It is very probable that, just as in the case of cavities in the lungs where perforation of the pleura takes place, so here a partial perforation had occurred, but its effects were confined by adhesions, and the result was the small abscess around the appendage; but, after a time, the inflammation extended from the abscess and became general over the peritoneal surface. This case reminds me very forcibly of one in which there was an ordinary diverticulum of the intestine, at the very extremity of which was situated a small ulcer, which had caused perforation. There were other ulcers in the intestine of the same nature as those in this case, but none of them seemed near causing perforation. Considering how rarely these so-called tubercular ulcers lead to anything like general peritonitis, and how seldom any actual perforation occurs, we must look on the relations of the vermiform appendage in the one case, and those of the diverticulum in the other, as predisposing to this complication.

CASE III. Adhesion of the Extremity of the Vermiform Appendage to the Ileum. Incarceration of the Intestine.—Jane H., aged 60, was admitted to the Royal Infirmary on July 1st, 1871, under Dr. McCall Anderson. About three weeks before, she had first experienced a severe pain in the right hip and in the abdomen, especially the right iliac fossa. This continued till admission, becoming neither better nor worse, and she described it as a smarting pain, leaving off at times. About twelve days before admission, an eruption of small blisters appeared on the hips, and the crusts remained like those of herpes zoster on admission. The right iliac fossa was very painful on pressure; the bowels were stated to be regular. On the evening of August 7th, she became much worse, and next morning was in a state of collapse, from which she did not recover, but died at 2.30 P.M. On opening the abdomen, the peritoneum was found to contain about a pint of red fluid. The lower part of the ileum was at once seen to be of a very deep red colour, and distended with gas and fluid faeces. The rest of the small intestines was also somewhat distended. The deeply congested appearance of the ileum was distinctly defined, commencing abruptly about two feet above the valve, and ending about an inch above that structure. Just above the commencement of the congested part, the free extremity of the vermiform appendage was firmly adherent to the peritoneal surface of the ileum, and the whole ileum beneath that point had slipped beneath the appendage, which thus acted as a constricting band. On opening the ileum, the affected portion was seen to be intensely hyperæmic in all its coats. The general peritoneal surface was distinctly but not excessively hyæmic.

In this case, some doubts may exist as to the exact course of events. The fatal issue seems to have been directly caused by the incarceration of two feet of the small intestine which had passed under the vermiform appendage; but the exact significance of the earlier symptoms, which existed for eight weeks before death, is more difficult to be sure of. These symptoms all pointed to some affection in the right iliac region or neighbourhood of the right hip. Now, the adhesion of the vermiform appendage was so firm that we can hardly suppose that

it was only of two months' duration, or that these symptoms were due to an inflammation resulting in this adhesion. It is difficult, however, to make any very certain statement in such a case, and possibly these symptoms may admit of such an explanation. On the other hand, the portion of small intestine may have been gradually slipping beneath the appendage during these weeks; but, as the passage was pretty wide, although the gut may have been subjected to considerable pressure and irritation, yet no actual obstruction may have taken place till just before death. This seems, on the whole, the more likely explanation, as the pain was stated to have come on suddenly, and to have been very severe. The occurrence of an attack of what appears to have been herpes zoster, in connection with this local irritation, must be an interesting point in connection with the supposed relation of this disease to affections of the nerves. The fatal issue then, was, the indirect result of a simple adhesion of the tip of the vermiform appendage to an approximate loop of small intestine; and the observation readily suggests itself, that if the exact condition could have been made out during life, a very simple operation, though a dangerous one, might have relieved the patient and averted the unfortunate result.

CASE IV. Hydrops Appendicis Vermiformis. Transformation of the Appendage into a Large Cyst.—In this case, the very marked affection of the appendage was only discovered after death; no symptoms during life having attracted attention to its existence. The patient died of renal disease and pericarditis. The vermiform appendage was converted into a large bulky cyst, whose general appearance is shown in the diagram. The shape of the cyst may perhaps be best described as somewhat like that of an egg attached by one of its extremities to a short cylinder. The oval part formed the free extremity, and the other end was attached to the caecum by a short process at right angles to the long axis of the cyst. The cyst, which had thus an elongated shape,

measured about five and a-quarter inches in length, and about two inches in thickness at the widest part, which was the middle of the egg-shaped portion. The cyst had a short mesentery, which was attached above to the terminal portion of the ileum, and thence passing downwards, became broader as it spread along the upper border of the cyst. The cyst-wall was generally pretty thick, comparable in this respect to the wall of the half-distended large intestine. At some parts it was thicker than at others, and in one of these places had an opaque white, almost aponeurotic appearance. This part was towards the attached end, and is outlined in the sketch. A few vessels ramified on the surface of the cyst. The contents were a yellow tenacious material, which did not flow out on a small aperture being made, and which appeared to be of about the thickness of jelly.

Cases of this kind have been described, and it is generally supposed that they originate in an obstruction of the orifice of the appendage, and the accumulation of the secretion within the canal. The obstruction may be due to the existence of a foreign body, such as inspissated faecal matter, or mucus. The obstruction leads to accumulation of the mucous secretion of the appendage, which dilates the canal and converts it into a cyst. With this dilatation, the coats usually become thin,

and by and bye ulceration occurs and perforation, with, it may be, a general peritonitis. In certain cases, however, and this seems to be one, the coats become thicker as the dilatation proceeds, and the secretion is retained while the cyst attains very large dimensions. The thick colloid contents represent the mucous secretion of the glands of the appendix.

CLINICAL REMARKS ON A CASE OF STRANGULATED FEMORAL HERNIA.

By T. H. BARTLEET, F.R.C.S.,
Surgeon to the General Hospital, Birmingham.

For the following brief notes of the case, I am indebted to Mr. Shipworth, Resident Surgical Assistant.

Thomas Jones, aged 43, married, a smith, was admitted November 10th, 1874. He had had a swelling in the right femoral region, which occasionally disappeared, for the last seven years. On November 1st, the swelling increased without any special cause. His bowels were constipated; and he took aperient medicine, which produced two motions. On November 2nd, he vomited several times. On the 3rd, the vomiting continued, and he was unable to pass flatus. On the 4th, he described the vomiting as being fecal. Constipation and fecal vomiting continued until his admission on November 10th, when he was found to have a small painless hard tumour in the right femoral region. There was no impulse. The belly was distended, but not painful or tender. The patient's aspect was distressed; his temperature was 99 deg., and his pulse 85. The taxis was tried with great care, but ineffectually. Under chloroform, a transverse incision of one and a half inches was made over the neck of the sac, down to which the intervening tissues were divided on a director. The seat of stricture was the falciform margin of the saphenous opening, a few fibres of which were divided; and the contents of the sac were returned, the sac itself not being opened. The sac, which seemed likely to be drawn up by violent respiratory efforts, was held to the wound by a hare-lip pin passed through the edges of the latter, and including a piece of areolar tissue attached to the sac. The wound was dressed and rolled in the usual way.

November 10th. Vomiting had continued two or three times after the operation. He took twenty minims of tincture of opium, which relieved the vomiting, and was followed by a good night. He had passed flatus. Temperature normal; pulse 75. He had no pain.

November 15th. There was slight discharge from the wound. He had passed a firm and very copious motion.

November 28th. The wound had been dressed with tenax, and was all but healed; it measured now barely an inch.

REMARKS.—The case seems to me to present the following points of interest: the length of time during which symptoms of obstruction had lasted; the lengthened duration of fecal vomiting; the mode of operation; the after-treatment.

Symptoms of complete obstruction had lasted for nine days. The condition of the hernial tumour did not justify the opinion that strangulation had lasted thus long. I believe that the hernia was, at the beginning at all events, *incarcerated*, not *strangulated*. Now, what is an incarcerated hernia? It is a hernia in which the constriction affects only the calibre, and not the walls, of the gut; that is, the passage through the intestine is entirely closed, but the intestinal walls are not sufficiently constricted to stop the circulation through them, and consequently to cause them to sphacelate.

Faecal vomiting was present for four days. This symptom, though a common one in long standing cases of strangulated hernia, is justly considered one of serious importance. It is supposed to be due to the long continued and ineffectual peristaltic action of the intestine above the stricture, inducing a backward current of the contents of the bowel in the centre of the tube.

The Operation.—I have for some time given up the long vertical incision over the whole or greater part of the sac. I make a short transverse incision over the neck of the sac, by pinching up the integuments and transfixing; the incision being rarely as long as two inches. I divide the tissues on a director until I am able to insert a nail under the stricture. I find it rare, even in old standing and in inguinal hernie, to be unable to relieve the stricture without opening the sac. Occasionally the stricture is caused by a few fibres in the sac; and these I have, in one or two cases, very carefully divided from the outside instead of from the inside of the sac.

Herniotomy without opening the sac is an operation free from danger. No important tissues are cut through or displaced. The danger, as far as the operation is concerned, is due to the opening of the sac; for we

then make an open track for the admission of air, and sometimes of fingers, into the peritoneal cavity. I think needless alarm is often felt about the condition of the bowel, or of its strangulation by a band or by omentum, when the sac is not opened. In cases of recent strangulation, it seems to me as great a mark of unwisdom to open the sac to examine its contents, as it would be to trephine the skull to look for a possible clot underneath, in every case of injury of the skull with insensibility. Opening the sac is a *certain* risk; leaving it unopened is an *uncertain* risk. Moreover, in recent cases of strangulated hernia, it is customary to attempt reduction by taxis. Now, if it be safe to reduce a strangulated hernia by taxis, it is surely safe to do so by an operation which is as safe and simple as is extraperitoneal herniotomy. I am aware that the present case is not one of *recent* strangulation. The symptoms of obstruction and even fecal vomiting had lasted many days. It may be fairly asked why I did not deem it necessary to open the sac and examine the condition of its contents. My examination of the hernia before and during the operation did not favour the belief that it was gangrenous. Pain was not, and had not been, complained of. The integuments were not emphysematous, cedematous, or red; the sac was not flaccid. Had the sac or its contents been long gangrenous, the superficial tissues would have resented the presence of dead matter, as of any other foreign body. Unfortunately, there is no way of telling whether or not the contents of the sac are *just dead*; and I consider it better, in the absence of definite symptoms, to face this risk rather than that of peritonitis, so frequently consequent upon opening the sac. After I had returned the contents of the sac, the violent efforts of vomiting seemed likely to draw the sac itself up into the abdominal cavity. This was undesirable, since, had symptoms of strangulation still continued, I might have wished to open the sac and to bring into view the intestine or omentum it had contained, and which, in the paralysed state of the intestines, would almost certainly be found lying near the crural ring. I therefore kept the sac near the wound by transfixing a tag of areolar tissue attached to it (not the sac itself) by a hare-lip pin, with which I closed the wound. The necessity did not arise in this case, but the manœuvre might be useful in other cases.

With regard to after-treatment, one dose of tincture of opium relieved the sickness, and gave a good night, which the novelty of the patient's position in hospital might have prevented. After this, he had no medicine—above all, no aperient. He was kept to milk and broth diet until his bowels were open, which they were on the fourth day after the operation and the fourteenth day of constipation. The wound was dressed with tenax—an excellent dressing for these deep wounds, as it prevents the accumulation of pus, and consequently favours the contraction and healing of the wound. (*Brit Med Journal*)

THE SLEEPING SICKNESS OF WESTERN AFRICA.

By ALBERT A. GORE, M.D., F.R.C.S.I., SURGEON-MAJOR.

SOME time since, I read, in the "Notes and Queries" of a contemporary, a few brief remarks on this rare disease. As the subject is one of some interest to those who may travel in these distant regions, and to the medical officers who have to treat our West Indian soldiers, I have jotted down the following *résumé*, which may probably contain a summary of all our present knowledge on the matter.

Lethargy, from the Greek terms *λῆθη* and *ἀργία*, is placed by the older writers under their division *Neurotica*, and defined as a "mental and corporeal torpidity, with deep quiet sleep". The occasional causes being congestion or effusion in the brain by violent mental commotion, as that of fright or furious anger; by retrocedent gout, or repelled exanthems; but more generally by long continued labour of body or severe exercise of mind, cerebral exhaustion. Celsus regarded it as a nervous affection; Forester and Cheyne as chiefly dependent upon plethora or congestion. According to Mason Good, it is not unfrequently a strictly nervous affection connected with an irregular or debilitated state of the mind. The common causes of sleep, therefore, whether natural or morbid, are in many cases causes of lethargy. The older writers classified the disease under three heads.

(a.) *Lethargus absolutus*, or genuine lethargy, without intervals of sensation, waking, or consciousness.

(b.) *Lethargus cataphora*, or remissive lethargy, with short remissions or intervals of imperfect waking, sensation, and speech.

(c.) *Lethargic vigil*, or imperfect lethargy, perfect lethargy of the body, but imperfect lethargy of the mind, wandering ideas, and belief of wakefulness during sleep.

The first variety of the ancients is the later "constitutional lethargic slumber" of Blanchet and other French observers. Examples have

occurred lasting forty days (Platt), seven weeks (Bang, Collection), months (Blanchet), at intervals during five years (Good). In one instance it was stated to have resulted from insolation, or exposure to the direct rays of the sun. The second variety, the *coma somnolentum* of many writers, has been an accompaniment of many fevers and other diseases of great debility. In a case mentioned by Good, the patient, a young lady of delicate constitution, during the irregular remissions, sighed, ate reluctantly, and instantly relapsed into sleep. The third variety is the typhomania of the Greek writers, and an occasional sequel of fevers and other causes of great nervous debility, where the sensorial power has not recovered its regularity of current or stability of balance. In a case mentioned by Cook, in his treatise on *Nervous Diseases*, the paroxysms ultimately ended in derangement of the mind. Some of the symptoms of that convulsion of the mind known as *melancholia attonita*, or its paralysis, as seen in acute or chronic dementia—viz., an impassive or motionless body, vacant stupid expression, involuntary passage of urine and feces, and a passive resistance to the action of others, are occasionally seen in the last stages of African lethargus.

My attention was first called to this curious disease when quartered upon a solitary island at the junction of the Rio Jaba and Rio Grande, in Portuguese Senegambia, in 1866. I had just returned from shooting, when a native was brought to my bungalow with an enlargement of the glands of the neck, which he was anxious to have removed. My servant, a Portuguese, informed me that he stated he was afraid he was about to get the "sleeping sickness". Upon further inquiry, I found that this was really the case, and that among the people of the neighbourhood this enlargement of the glands was considered a premonitory sign of African lethargus. My servant, who appeared to be quite *au fait* with the subject, further informed me that the native doctors always excised or destroyed the enlarged lymphatic glands as a measure of precaution, a process accounting for the numerous scars which marked the neck and other parts of the bodies of their patients. Upon returning to headquarters, and looking over our medical records, I found a case of the disease, which terminated fatally, noted down as early as 1833, at Sierra Leone, by Assistant-Surgeon McDonald, of the Royal African Corps, the patient being a private of his regiment; and, three years later, the following interesting and graphic description of another, by Dr. William Fergusson, surgeon of the corps, principal medical officer, and afterwards governor of Sierra Leone. It is headed "Lethargus".

Dr. Fergusson goes on to say: "It is a disease rarely met with here, and it occurs more frequently among the class of recently arrived liberated Africans than among any other body of the population. In the course of the last fourteen years, I have seen four cases of it, three of which were liberated Africans, and one a maroon. There was no variety in the symptoms of these four cases, and one only of them terminated favourably. The disease substantially consists of a strong and irresistible desire, or rather tendency, to fall asleep under any circumstances—an inability to keep awake is perhaps the most suitable definition. I have not seen it tested under the circumstances of passion or strong mental emotion, and am rather inclined to think that the passions are obliterated, as it were, in the general tendency to rest which seems to pervade the whole system. The maroon boy above mentioned used to fall asleep standing, amidst all the noise and excitement of a school conducted upon the monitorial system; and I have seen Private George Gannus, 2nd West India Regiment, the subject of this case, lying fast asleep with a mouthful of half-chewed victuals in his cheek; he had, in fact, fallen fast asleep, while eating his dinner. He was taken into hospital on March 1st, 1836; his comrades stated that he was always sleeping; that, whenever he sat down for a few minutes, he was sure to fall asleep. He was well purged, and on the 5th discharged cured. He was again brought to hospital on the 15th with the same complaint of constant sleepiness; his look was stolid. He made no complaint of pain; ate well. The pulse was 72; tongue clean, except a small spot of fur in the centre. A dose of drastic medicine was given, and repeated upon the second day. He was kept in hospital until April 5th, during which time he had a dose of colocyth and calomel about once in three days. He was discharged to duty, not having had any return of the sleepiness. In the early part of May, symptoms of another return of the disease became manifest, necessitating his being again taken into hospital on the 8th of the month; recourse was again had to the system of drastic purging which had succeeded so well on former occasions. It was, however, but too clear that the drastic mode of treatment had entirely lost its power. Five dozen of leeches were now applied to the forehead and temples, and a large blister to the shaven scalp, without any advantage. He slept almost continuously; when roused at meal-times, he made a scanty meal, and sometimes fell asleep over it. He was now put upon the

use of a small daily dose of calomel, and a blister was applied to the nape of the neck; his bowels had all along been kept free, and, up to this period he had made regular use of the night-chair. He now slept constantly; decubitus on his back; his alvine evacuations were passed involuntarily. He sank gradually, and died on June 1st.

"The dura mater was found to be in a healthy state; the arachnoid membrane was red, and highly vascular; this condition was not confined to any particular part of it, but prevailed throughout. The pia mater appeared healthy; the substance of the brain was particularly firm, and not one drop of blood appeared on a section of any part of it; the sinuses were unusually deficient in the quantity of blood; the lateral ventricles contained about a drachm and a half of serum; the thoracic viscera did not present any unusual appearance. In the stomach were found many patches of a red colour near the pylorus; these did not extend into the duodenum. A portion of small intestines, about three feet in length, was of a very dark colour, and the calibre of the canal at that part was much contracted; this part of the canal contained a considerable quantity of thick sanguineous serosity, and its mucous coat was highly injected. The liver, spleen, and kidneys were in a healthy-looking state."

The following is the only other case the details of which I have been enabled to obtain: they are given by Surgeon-Major Morpew. "No. 166, Private J. M., 1st West India Regiment, twenty-eight years of age, was admitted into the military hospital, Nassau, Bahamas, June 27th, 1865, for dementia and lethargus. Some months prior to admission, he had been in a singular way. When on guard duty, he was constantly in the habit of falling down in a semicomatose state, and, upon the return of consciousness, he would invariably state that he had seen a "spirit". This delusion had unquestionably something to do in bringing him to the state in which he was upon admission. From his appearance, I was of opinion that he would become a subject of the disease, so common among Africans, called lethargus; and into a lethargy he fell on the 10th instant. For a few days previously, he spent most of his time sleeping, but during the last eleven days of his life he never awoke; he expired about one o'clock in the morning. All medical treatment in these cases is useless as a rule, and in this case was not tried beyond attending to the state of the alimentary canal. Two years subsequently, a private of the same regiment died in the goal at Freetown suffering under symptoms of lethargus. This delusion of having seen a spirit is a common one among Africans." Dr. Morpew's remarks as to the fatality of the affection is fully borne out by statistics to be presently quoted.

The next contribution to the history and pathology of the disease is from a writer in the *Medical Times and Gazette* of the 24th October of the present year. He goes on to state: "The first intimation is a swelling of the glands about or around the neck, accompanied by a gradual inclination to sleep, which increases; and the person so affected will fall asleep at all times and in all places, no matter what he may be doing—working, eating, walking, talking, or anything else, only awaking at short intervals. Sometimes the body swells in the progress of the disease, and at other times in its first stage. The skin becomes dry and dusty; the strength palpably decays; and the most massive form becomes reduced. This continues for six or twelve months, more or less. Just before death, the patient suddenly ceases to sleep; this is the forerunner of death always. I have never known a Congo die of any other disease. It carries off many natives; and even the Americo-Liberians do not escape from it." The Congos to whom the writer refers are among the lowest type of negro in mind and body inhabiting the shores of West Africa. When they were liberated in large numbers at Sierra Leone, the disease came far more frequently under observation in the colonial hospital, as will be seen from the following returns. For the four years ending March 31st, 1850, 112 cases of lethargus or sleeping sickness were treated; for the seven years ending December 31st, 1866, only 67 were treated. Of the 179 cases admitted, 132 died, 47 recovered—a very high ratio of mortality. Burton, and most other writers on Western Africa, allude to the disease as a medical curiosity; the former states that Europeans have died of it. The cases of African sleeping sickness which I have seen in the colonial hospital at Sierra Leone, two of them in the last stage of the disease, presented similar features to those already described; the patients lay upon a mat sleeping their existence away. One was very much emaciated; he lay quite motionless, and apparently unconscious; only appeared to notice when severely shaken, then merely raised the eyelids and gazed vacantly. The splinters had already become relaxed; the urine and feces were passed involuntarily; and for some days previous to death he lay quite passive, refused all nourishment, and died at last, as in the cases already described. While recently on the Gold Coast, I had under treatment in hospital a private of the 2nd West India Regiment, who appeared to suffer under lethargic prodromata. He

was constantly sleeping, and with difficulty was made to take food and medicine. He afterwards passed from under my notice.

The treatment of African lethargy has been, as a rule, eminently unsatisfactory in the severer forms. Stimulants, alteratives, depurants, and counterirritants have equally failed to arrest the onward progress of the disease. Celsus, who contemplated lethargus as a nervous affection, confined himself to external and internal pungents, shaving the head, fomenting it, and afterwards applying some rubefacient epithems. Others, such as Good, advised cupping, blisters, purgatives, the voltaic current from the occiput to the sacrum, and metallic tonics. Such a line of treatment appeared to afford a temporary relief. If the glandular enlargement observed were due to leucæmia and hypertrophy of the spleen, conditions sometimes associated with lethargic symptoms, quinine, ferruginous tonics, and antiperiodic medicines might be of value. Except by supposing that the enlarged lymphatic glands in the vicinity of the arteries of the neck pressed upon and deranged the cerebral circulation, thus diminishing and interfering with the blood-supply of the brain, one could not reconcile the Portuguese idea of its pathology with the facts observed. The etiology of the disease is still curiously obscure.

REPLY TO DR. MACLEAN RESPECTING MALARIAL FEVERS.

By T. INMAN, M.D. Lond.,

Late Lecturer on Medicine at the Liverpool Royal Infirmary School of Medicine;
Consulting Physician of the Liverpool Royal Infirmary.

IN looking over Dr. Maclean's communication in the BRITISH MEDICAL JOURNAL of December 19th, I find that the author speaks of Dr. Oldham and his followers not attempting to explain the fevers suffered from in the Ashantee expedition. As yet, it is probable that a sufficient time has not elapsed for Dr. Oldham to obtain the necessary information, he being in India. And this cannot be wondered at; for, though anxious to obtain definite knowledge myself upon the subject, I have been unable to find any. As a friend of Dr. Oldham, and one who has taken a deep interest in his theory, I venture to stand forwards on his behalf until he is able to see Dr. Maclean's attack and to parry it for himself.

In writing this, it is not my intention to support Dr. Munro's hypothesis that "certain electrical conditions" influence the productions of so-called malarial diseases; but I most cordially agree with him "that there is no such poison as malaria".

I may, at the outset, state that I have not had any personal experience of malarious disease; but I have travelled more than once through the most malarious districts of Italy, and have had the advantage of conversing on the subject with individuals whose business has led them to reside in Sierra Leone, the large trading stations on the great Western African rivers, the swamps of the Southern United States, and other parts of the world, which are said to be most fatal to human life in consequence of "malaria". My informants have been both medical and lay, and what testimony I have got has not been brought out by the putting of "leading questions". I am not, therefore, simply "a parlour-judge".

As I am perfectly familiar with Dr. Oldham's exhaustive treatise upon *Malaria*, the first thing which strikes me in Dr. Maclean's letter is, that the critic does not know the work of which he speaks slightly. Had he done so, he would not have committed himself to the illogical arguments which he uses. In the paragraph wherein he speaks of fevers breaking out at Hong Kong and Paris, consequent upon turning up the soil for building purposes, there is the expression, "If the soil did not give birth to a fever-generating poison in all or any of the above cases, what did?" This reasoning is on a par with the assertion that "Tenterden steeple produced the Goodwin sands; and, if it did not, what did?" Dr. Maclean wants an explanation of this difficulty of his. Dr. Oldham has already given it; but I would desire to supplement what he has said by calling attention to the vicious style of observation and argument exposed by Lord Bacon nearly two hundred and fifty years ago. The "idols of the tribe", to which that learned author referred, include a propensity to stick through life to opinions adopted in youth, to explain away everything which militates against them, and to give undue weight to apparent evidence in their favour. Dr. Maclean has not yet learned to avoid this pitfall. Dr. Oldham very justly lays down the law, that the cause which produces "malarious fevers" in rocky and sandy districts, where there is no vegetation and *no soil whatever*, must be analogous to the cause producing the same effects elsewhere. This is a strictly logical assertion.

If, then, Dr. Maclean declares that "soil" produces malarious disease,

he must show that such complaints never occur in the Sahara, on bare mountain-rocks, and on ships at sea. But at Aden, where there is no soil, and in rocky tropical localities, fevers are as common as and even more severe than on the Pontine Marshes or the Maremma district. E.g., on the march to Magdala in East Abyssinia, Consul Hutchinson, in his recent work on Peru, has mentioned that ague and malarious fevers have occurred more than five thousand feet above the sea amongst the navies digging a proper bed for a new railway. If Dr. Maclean had seen his observations, he would not have needed to inquire, "If the soil did not produce the disease, what did?" for the consul, himself a medical man, and one who has had intermittent fever nearly forty times, gives a very feasible account of the reason why.

To explain all this, however, to Dr. Maclean and the members of the British Medical Association, would require almost a treatise. I may be pardoned, then, if I try to explain Dr. Oldham's views in a short manner. The gist of his argument is, that the so-called malarious diseases are due to cold or chill after exposure to great heat, especially after it has been accompanied with exhausting labour.

Than this hypothesis, nothing can be more simple. Every doctor in Great Britain is aware how frequently bronchitis, pneumonia, and other severe affections, are attributed to cold—borne by a person who has been previously exhausted by exercise in a hot atmosphere—or by the sweating which labour produces, even in winter. If we see a navvy, teeming with perspiration, lie down and sleep in a draught, or on a cold stone, we say to ourselves, "that he will be lucky if he do not require a doctor".

There is, then, *a priori*, something reasonable in the idea, that an excess of heat and cold will produce analogous and more severe results. Now, in England, the difference between the day temperature and the night, is barely twenty; 90 degs. in the shade by day is about 70 degs. in the shade by night; but, in malarious districts, the temperature by day for those working in the sun (and it is those who get the fever), is about 140-150 degs.; at night, this falls to about 50-45 degs. Again, it is known, that during frost, such as the French Army experienced in the retreat from Moscow, the cold is bearable; but when a thaw sets in, and the cold is moist, not dry, frost-bite is common.

Every notoriously malarious district is marshy; consequently, those who live therein, are subject to more severe variations of temperature than those who live in dry places. During the day, the hot air over a marsh or lagoon is saturated with dissolved water as soon as the sun is low, and still more after it sets. This water is *precipitated*, and we have a cold dew—did ever anyone hear of a hot one?

I have emphasised the word "precipitated" because it involves a most important point. If the word be used correctly, there can be no emanation from the ground during the time the aqueous particles are falling. As I presume that Dr. Maclean is familiar with the cause of dew, I need only point out, that terrestrial emanations only take place by day, and must cease at night; yet night is the fatal half of the four-and-twenty hours. Night is also the coldest part of the day in every country, and the cold is most intense when there is nothing to intervene between the earth and stars.

It is well known that the Pontine marshes are only dangerous after sundown, and only then to anyone who cannot keep himself warm. Dr. Oldham tested the malarious theory, by sleeping, for many months together, on a bed placed in a swamp, and barely two feet from the ground. There were atrocious stinks, and his nostrils suffered accordingly; but he always wrapped himself up warmly, and never got fever that way. He did get it once before, and that was in the room of his superior officer, and under the following circumstances. He had ridden, in the heat of an Indian day, to deliver a report, and was perspiring; when he arrived, the room occupied by the colonel was cooled with a punkah, and the doctor was suddenly chilled, and could not leave the house, for he instantly was struck down by fever. His book contains many such cases.

This will serve to introduce to Dr. Maclean the reason why fever has attended disturbance of the soil. Men work hard, under a hot sun during the greatest part of the day; when night comes they are tired, glad of something to drink, take too much, and sleep too heavily, to be awakened by the cold. The blood has, so to speak, been boiling all day, at night it is chilled almost to the freezing-point—hence the fever, which may show itself as intermittent or remittent; or as the attendant of dysentery, hepatitis, pneumonia, etc.

Consul Hutchinson in Peru noticed these causes in operation, and was not surprised at their results. In some parts of South America, to "catch a cold" is "to get an ague", the expressions being synonymous.

In the Ashantee expedition, the alternation between daily heat and moist nightly cold was enormous; and any one who has read of the excessive exertion, and consequent fatigue, undergone by the men, whilst

the sun was above the horizon, and the cold which they had to endure when that source of heat had set, can readily understand why the fevers which the soldiers had were so severe. Had the men not been partially sheltered, by the forests which they traversed, from the radiation of their heat into space, matters would have been infinitely worse. Even horses who sleep in the open air in Arabia become diseased; all the valuable ones are sheltered during the night by some sort of cover, which prevents chill. Dr. Maclean, had he read Dr. Oldham's book, would readily see how forcibly his own statements support the latter's doctrine; e.g., Dr. Maclean quotes from Colonel Gordon how the blacks of the Soudan go indoors at dusk, light fires, and try to live in the smoke. Surely, he will acknowledge that the smoke of a fire is warm, and that the effect of the fires, kindled in every hut, kept by the nearly naked Africans, is to make them, as respects warmth, somewhat comfortable. This warmth it is that prevents their getting fevers. A friend of mine, who lived at Sierra Leone for years, never had even a touch of fever; for, during the wet season, he habitually warmed his rooms with a stove, and always was warmly clad.

These observations have a practical bearing; for, if there be such a poison as "malaria", we cannot absolutely guard ourselves against it; but, if it be true that the diseases attributed hitherto to malarious miasms are really due to severe chill after great heat or great exertion, we can arm ourselves against them. How severe and sudden may be the effect of chill, the following will show. A medical friend of mine, living in Cheshire, saw, one day in May, a maid of his, who had been engaged in washing, and was bathed with perspiration, standing in a draught of air to cool herself. He sent her away from the door, but, ere the day was over, the woman had general dropsy; the urine passed in twenty-four hours amounted only to half an ounce, and was full of tube-casts, though not albuminous. Surely, no one would say that she had imbibed a poison from the soap-suds; nor, had she been delving, would one say that she had been poisoned by the terrestrial effluvia. Until the teachers of our youth have a larger capacity for inquiring into old facts, with the light of modern science, and for basing their instruction upon logical deductions, rather than what are called "time-honoured facts"—because they have been asserted for a century or two, though not facts at all—the practice of our profession will not improve, not being based upon sound knowledge.

If a soldier be taught that agues, etc., come from "soil", he takes no precaution when no "soil" is present to produce them; and then, when a *medico* finds his detachment ill with intermittents or remittents, he feels helpless to prevent the spread of the disease. On the contrary, had he been taught truly, he would study the air as well as the earth, and remember the dictum of the Indian colonel, who said to Dr. Oldham, "You doctors may talk of marsh-poison as you like; but my experience has taught me that hot days and cold nights are certain to produce fever".

THERAPEUTIC MEMORANDA.

IODIDE OF POTASSIUM IN ASTHMA.

THE notes of the following case, showing unusual results from the administration of iodide of potassium, may be sufficiently interesting to warrant me in asking for their insertion.

Last summer, I was called to see A. B. She complained of cough accompanying attacks of asthma, coming on regularly about 2 A.M., and lasting for an hour or two. I ordered the iodide in four-grain doses, with ipecacuanha wine and squills, every three or four hours. The asthma was better during the night; and the next day the cough and breathing were also better, and the medicine was taken less regularly. The same evening, my patient was seized with intense pain across the loins, more severe on the left side; also inability to pass urine unless in very small quantities, and accompanied with very great pain. Relief was obtained from the use of hot baths, diluent drinks, and large doses of the bicarbonate of potash and liquor potassæ. During the next fortnight, no medicine was given, the asthma continuing better; but at the end of that time a fresh attack occurred. The iodide was given in the same doses, and was followed in a few hours by threatenings of the same pain and discomfort. A short time afterwards, two-grain doses of the iodide were tried; but a few doses were sufficient to show that the system would not tolerate the medicine, although after its use the asthma was invariably better. My patient complained of no other symptoms peculiar to a state of "iodism", unless a very salt taste in the mouth while taking the iodide. The urine was highly acid while the pain lasted, and relief was only obtained as this secretion became alkaline. This bears out the theory that rheumatism, eczematous eruptions, or gravel, often replace asthma, or may in turn be replaced by it.

My patient has inherited a strong rheumatic tendency. She also suffers from a patch of eczema on one arm, which always followed the fortunes of the asthma as it got better or returned. This case seems one in which asthma and eczema act as safety-valves for a system having a strong rheumatic diathesis; and the curative effects of the iodide on the former serve to intensify the latter by increasing the amount of uric acid to be eliminated by the kidneys. Iodide of potassium acts by promoting the action of these glands, most probably by its primary power of causing the absorption of additional waste nitrogenous matters into the blood, which are eliminated partly as uric acid. Hence we can understand how this additional work, thrown on glands already injured by constant work at high pressure, should have the effect of paralysing their efforts at elimination—should be followed by a severe attack of gravel.

J. MITCHELL WILSON, M.B., Chatteris.

THE THERAPEUTIC VALUE OF IODIDE OF POTASSIUM.*

AS I have for several years paid considerable attention to the action of iodide of potassium, I venture to offer the following remarks as supplementary to Mr. Spurgin's article in the JOURNAL of September 5th, 1874. This medicine has been accredited with many modes of action: thus, in struma as an alternative, in asthma as a sedative, and in diphtheria as an antidote. To all these titles it may have a claim which different observers may think fairly borne out; but certainly the one distinct and indisputable action of iodide of potassium which I have noticed, is that of *stimulating the mucous membranes*; thereby influencing their action and promoting their secretions. Thus, as the results of its use, there are pain and sense of fulness across the eyes; increased secretion from the nares, mouth, fauces, and bronchi; leucorrhoea and menorrhagia are greatly aggravated; and in persons very susceptible of its influence, diarrhoea is induced, not so much of a cathartic as of a dysenteric kind; that is, rather an increase of mucus with tenesmus than of serum with catharsis.

In a person suffering from an attack of chronic winter cough, the first symptoms are great difficulty in breathing, amounting to a sense of suffocation; hard, dry, racking cough, which the patient says he cannot subdue; while he expresses a belief that relief would be obtained if something could be brought up. The suffocation complained of has been attributed to a swollen state of the air-passages, obstructing the respiration; but there is a fair probability that the dry congested condition of the membranes is unfavourable to the interchange of gases requisite for blood-aëration, and the situation of the patient such that, however he may fill his lungs, his sufferings remain unrelieved. Whatever the actual state of matters at this point, certain it is, that as soon as expectoration sets in, the breathing is improved; and, although the disease has by no means gone, the patient is so far better. Many hours of severe suffering may be obviated by taking advantage of the power of iodide of potassium to restore and promote the secretion of the bronchial membranes, thereby greatly relieving the congested blood-vessels, producing comparative tranquillity of breathing, and getting the patient over the first stage of the disease much sooner than he otherwise would. This, however, is possibly not its only value. For, here again, however opinions may differ as to the cause of the emphysema which from an early period exists in these cases, no one can have witnessed the severe and straining cough at the onset of the attack, without feeling that it is at least possible for either dilatation of the air-cells or rupture of the tissue of the lung to take place—complications much less likely to occur, so far as the cough is concerned, when the sputum has been rendered easier of expectoration and the irritability of the congested membranes removed by free secretion. It is further to be remarked that the action of the iodide of potassium changes the purulent character of the sputa in chronic bronchitis to a much healthier appearance. From this view of its operation, it follows, as a matter of course, that when free secretion of mucus has set in the medicine should be used with caution or altogether abandoned; and, therefore, when in the treatment of bronchitis—capillary or chronic—moist *râles* are fairly established, the further management of the case should be on the principle of preventing a too abundant secretion, at the same time employing such means as may assist expectoration and maintain the strength.

In asthma, iodide of potassium is recognised as a valuable medicine. Here the explanation of its action generally given, is that of a sedative relieving bronchial spasm; evidence of the presence of spasm being found in the wheezing and whistling sounds heard in auscultation,

* Extracted from a paper read before the Glasgow North-Western Medical Society in the winter of 1872.

Either of these sounds, however, fairly suggests the question, how far a fit of asthma is dependent on, or, at all events, greatly aggravated by, an abnormally dry condition of the mucous membranes, acting as in the diseases already mentioned, which is relieved by the iodide restoring the secretion.

In diphtheria, iodide of potassium is looked upon by many practitioners as the best remedy we possess. Here its alterative and sedative actions are laid aside, and we have it doing duty as an antidote to the diphtheritic poison: although, so far as can be seen, it exercises no new influence. In this disease, while there is free secretion from the nares, the breathing and cough-sounds are usually not very alarming, nor is respiration greatly impeded. It is not till the nares become dry—and doubtless the pharyngeal, laryngeal, and tracheal secretions diminished—that the formation of false membrane proceeds with fatal rapidity; hence, it does not seem too much to assume, so long as an iodide can keep up these secretions in such profusion as to prevent them from remaining on the parts sufficiently long to undergo membranous change, so long will its action be beneficial. The idea of an antidote might be more satisfactory; but it cannot be substantiated; nor does this view of its action afford any indication as to what extent the medicine should be given; whereas, by paying attention to the degree of influence exerted upon the mucous secretions, the dose and frequency of administration may fairly be ascertained; if not, indeed, the knowledge acquired as to whether or not it is doing any good.

Without at present entering into a consideration of the influence of iodide of potassium on digestion and assimilation—the real sources of its so-called alterative power—I may state as my conviction, that in all the various manifestations of struma, etc., where this medicine is of service it acts, so far as the iodine is concerned, in stimulating the mucous membrane of the stomach and duodenum—possibly, by sympathetic action, the liver and pancreas also—to increased secretion, whilst its alkaline base tends to promote the digestion of fat and starch.

For the dose no absolute rule can be laid down, because, in few respects, indeed, do constitutions and temperaments differ more than in the relative irritability of the mucous membranes, and, consequently, the power of iodine to influence their action. Persons of the bilious temperament usually resist its power to a wonderful degree, whilst in those of the lymphatic, sanguineous, and, above all, the nervous, a few doses of two grains each will often suffice to cause coryza, ptialism, pharyngeal irritation, and cough. In such diseases as diphtheria, the object should be to produce its influence as rapidly as possible, whilst in others, as struma, small doses long continued are preferable.

JAMES LAWRIE, M.D., Glasgow.

CLINICAL MEMORANDA.

THE ALBUMINURIA OF CHOLERA.

IN the report given of the inaugural meeting of the Epidemiological Society of London for the present session in the *BRITISH MEDICAL JOURNAL* of 26th December, 1874 (p. 815), the Secretary is represented as intimating that "Dr. Schimmel had communicated the important observation of the occurrence of *albuminuria* during the *invasion stage of cholera*"; and it is added that in all the cases observed "the albumen disappeared in two days". Upwards of twenty years ago, I drew attention to the fact that albumen is an invariable constituent of cholera urine, or nearly so, at later stages. As resident physician of the City Cholera Hospital of Edinburgh, I had no opportunity of examining the urine in the invasion or early stages. But careful systematic examination of the urine was made from the date of admission of each patient—usually in the collapse stage—with the following results as to albuminuria.

In the description of the chemico-microscopical characters of cholera urine, given in my *Clinical Notes on Cholera*, in the *ASSOCIATION MEDICAL JOURNAL* for April 21st, 1854 (p. 350), I state that "heat and nitric acid almost invariably prove the presence of albumen". This refers to the urine first passed after collapse, or drawn off by the catheter. "In the urine secreted when the renal functions begin to be duly re-established, the chief circumstances to be observed is the gradual disappearance of albumen.....The coagulability, as a general rule, disappears in from one to three days. Sometimes it continues for weeks, either regularly decreasing in intensity or intermitting, and re-appearing to a visible extent and at irregular intervals. In rare cases, the urine first passed has been said to be non-coagulable, while that subsequently voided may be albuminous."

In the section treating of the urine in a paper on the chemico-microscopical character of The Cholera Evacuations in Man and the

Lower Animals, published in the *Edinburgh Medical Journal* for February and March, 1856, it is stated (p. 164 of the reprint): "Whether voided naturally, or artificially drawn off, the urine first passed was... invariably albuminous;...at subsequent stages of the disease...the albuminosity gradually disappeared."

W. LAUDER LINDSAY, M.D., F.R.S.E., Perth.

POISONOUS MUSHROOMS.

I MAY add to the remarks by Dr. Drummond in reply to Mr. Cuffie, that the "eight or ten carefully chosen small young mushrooms" previously reported as eaten by my patient were freshly gathered, and of agreeable flavour and odour. I noticed a few fragments in the vomited matter having the ordinary black under-surface of cooked mushrooms, which could not be taken as evidence to prove that all the mushrooms eaten were free from poisonous qualities, even if the black under-surface do prove it, for it must be impossible to detect the external appearance of each mushroom eaten when it has been in the stomach at least six hours after the most careless mastication. Mushrooms were so plentiful on my patient's farm this year, that he frequently ate them without any previous pain or discomfort. On this account, I was in doubt if some of the apparently edible fungi eaten by him were not poisonous, and, for other reasons previously given, recorded the case.

Some authorities assert that it is difficult to detect edible from poisonous fungi; the practical question, however, is, Can cooks, or others who are not fungologists, detect poisonous from edible fungi by any certain rule? Is the popular notion correct, that all mushrooms of good odour are edible, if, when cooked, the under-surface be turned black; but if the under-surface turn light-coloured by cooking, they are poisonous? JAMES SEDGWICK, M.R.C.S., Boroughbridge.

REPORTS

OF

MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

GUY'S HOSPITAL.

SATURINE GOUT.

(Under the care of Dr. S. WILKS.)

A YOUNG man, aged 29, had worked since he was a lad in an oil-cloth factory, and had had much to do with white lead. On two occasions, he had had colic, but rapidly recovered under treatment. For some weeks, he had not felt well, being weak, and having flying pains about him; but he had continued his work until a few days before admission, when his present colicky symptoms appeared, which, increasing in severity, obliged him to come to the hospital.

On admission, his principal symptom was colic. He was a spare, pale young man, with a well-marked blue line on the gums; his left foot was painful, from inflammation of the ball of the great toe, which exactly resembled gout. The urine was slightly albuminous, and the radial artery was somewhat hard. He was first ordered opium, and afterwards-croton oil; and, when free of the colic, iodide of potassium.

Clinical Remarks by Dr. Wilks.—You may observe here two sets of symptoms; those directly due to the poisonous effects of the lead, and those due the gout induced by the lead. There are apparently, therefore, two different classes of symptoms due to lead, the direct and the indirect.

The symptoms due directly to lead are especially seen in the anaemia and atrophy, which persons long subject to its influence so markedly show. The atrophy may be due to the same action long continued, of which we make use beneficially in arresting hæmorrhage, and to the power which this metal exerts, through the nervous system, in contracting the arterioles, and so stopping the flow of blood. At all events, those who are poisoned by lead soon begin to waste away, and their muscles become smaller and smaller, until they are unable to stand, or raise their hands to their heads. This wasting of the muscles exactly resembles what is seen in the idiopathic progressive muscular atrophy, and, what is very remarkable, is amenable to remedies. The most extreme cases of muscular atrophy of this kind which I have seen have been cured, and more especially by galvanism; the continuous current being the most beneficial, as faradisation has very little influence over the wasted muscle. When a patient has muscular atrophy, dropped wrist, or colic, your suspicions of lead-poisoning are aroused; but I would have you to remember, that persons who are working continu-

ously in lead, or grinding; often suffer more rapidly and acutely from the metal; though, as no marked symptoms exist, you might easily overlook the cause. An example of the kind was lately under our notice in Mary Ward. A young woman had been working for some months in a lead-factory, when, becoming weaker and weaker, she was obliged to desist. When she came to the hospital, she was seen to have a pale waxy appearance, and was very thin. She complained only of debility. On mentioning her occupation, a blue line was found on the gums. We believed, therefore, that she was suffering from plumbism; we gave her iodide of potassium and nourishing diet, and she slowly regained her strength. Besides the anaemia and muscular atrophy, if the poisonous effects still continue, the nervous centres become affected, and the patient becomes generally paralysed and demented, or may have convulsions.

As regards the blue line, it is true that it is more marked on an inflamed gum around a decayed tooth, but in this case the line was well marked on a perfect set of teeth. It may be distinguished from the discoloration caused by carbon or other pigments, by the dotted appearance when seen under a lens. It is also said that when the lead circulates afresh in course of elimination by means of the iodide, that the patient may again have colic; this I have not noticed, but I have seen the blue line on the gums become much more marked under treatment.

One of the most interesting facts, however, in connection with lead-poisoning, is the production of gout, and apparently true gout; since the arthritic inflammation is due to the deposit of urate of soda in the joints. I have seen this gouty condition so very often, that I have no hesitation in confirming the statement of Garrod and others, by whom the remarkable connection was first observed; for, in several of my cases, the patients were young, and the ordinary predisposing and exciting causes were not present. I believe the observation is comparatively recent, for the great authority on lead, Tanquerel des Planches, does not refer to it. It is true, that he has a chapter on saturnine arthralgia; but he evidently does not refer to the joints, but to the limbs, as his equivalent expression is "*douleurs neuralgiques des membres*", referring to nerve-symptoms, which, I may tell you, were known to the Greeks as one of the effects of lead.

It is remarkable, too, that, not only is genuine gouty inflammation of the joints caused by lead, but of a necessity all the other usual concomitants of gout. Therefore, it is constantly observed that workers in lead not only have chalky joints, but have granular kidney, thickened blood-vessels, and the other changes constantly met with in gout, and which are almost synonymous with those of Bright's disease. In the present case, the urine was slightly albuminous, and the arteries slightly rigid and tense, suggesting the early condition of the change which I name.

This connection of lead and gout is so remarkable, that we naturally try to discover where it lies. We must first ask ourselves what we mean by gout. We generally mean by it that morbid condition of system which is due to the production of an excess of urate of soda, owing to a malassimilation of food. Now, this may occur under various circumstances from different causes; as, for example, the taking of too much nitrogenous food or wines, which directly favour its production; or, in other cases, from want of exercise, and consequent failure to get rid of the effete material; and, in other cases, to simple atony of the stomach in nervous and weakly subjects. The question, therefore, which we have to ask is, in what way lead-poisoning so affects the digestive and assimilative processes as to favour the production of this salt. This, we believe, is the question to be asked, and not a simple chemical one, because we find attacks of gout caused by disturbances of the nervous system, and relieved by such remedies as quinine, mineral acids, and colchicum; causes and remedies which can only indirectly affect the functions before named, and do not act by simple chemical methods. When we think we can solve difficult questions in pathology and therapeutics by known laws, let us ask ourselves how lead causes gout, and how colchicum cures it.

GLASGOW ROYAL INFIRMARY.

CASE OF CIRRHOSIS OF THE LIVER.

(Under the care of Dr. GAIRDNER; reported by Dr. FINLAYSON.)

Ascites and Oedema; Habits not Intemperate; Tube-Casts without Albuminuria; Paracentesis: five or six pints of Bloody Fluid removed. Death and Post Mortem Inspection: Atrophy of Liver; Congestion of Intestines, with Slate-Coloured Pigmentation of Colon; Fatty Degeneration of Renal Epithelium.—JOHN E., aged 47, hammerman, was admitted February 7th, 1874. The chief complaint was of abdominal dropsy; there was also some swelling of the feet. The patient had always enjoyed good health till one or two attacks of bronchitis about

ten years ago, from which, however, he recovered; and was fit for regular employment till April, 1873, when he brought up a quantity of blood by the mouth, without either cough or vomiting; the discharge lasted eight hours in a continuous flow, it was said, and its source remained in doubt, even after conference with Dr. Millar, who attended him. Since then, his strength had failed, and his colour had been bad; Dr. Millar, indeed, thought his complexion had been rather dingy for the last three or four years at least, although there was no suspicion of liver-complaint, or, indeed, of indigestion. He took food in small quantity (his teeth had been nearly all lost by an accident seventeen years ago), but he seemed to suffer no inconvenience from eating. Dr. Millar had attended him three or four months before admission for a feeling of gastric oppression without actual pain. Two months after this bleeding, the man was fit again for his work, and he continued at his employment till the beginning of January 1874, when the swelling began to appear in the belly and legs, and some abdominal pain was also experienced. On admission, in addition to various signs of bronchitis, marked peritoneal effusion and oedema of the lower limb were noted. The hepatic dulness seemed displaced upwards, but no very accurate results could be arrived at by percussion, owing to the distension of the abdomen. A few small spots of ecchymosis were found on the legs; there were also some traces of piles. There was no history of intemperance or syphilis. The urine was scanty, ten ounces or less in the twenty-four hours, and of good specific gravity—1.022; it showed no trace of albumen, although the tests with heat and nitric acid in the cold were frequently and carefully applied; on several occasions a few tube-casts were found, mostly perfectly hyaline, or with only a few pale granules contained in them; some, however, contained renal epithelium; pus-corpuscles were also found in some specimens. The urine usually contained copious deposits of red lithates; in some of the specimens, especially towards the end of the case, the colour was extremely bright. The tube casts in the non-albuminous urine were brought repeatedly under the notice of the clinical class by Dr. Gairdner; due care was taken to avoid any fallacy from impurities. On February 19th, the usual tests for albumen gave a more doubtful result; no reaction was obtained by nitric acid in the cold, but heat produced a very slight turbidity, not dissolved by the addition of acid. There was some suspicion of jaundice in the patient, as the conjunctivae, as well as the skin, were yellowish; but, if present at all, the jaundice was certainly slight.

The treatment was by diuretics, including four ounces of gin, and by purgatives; but the distress and suffering of the patient increased from the growing distension, and much pain was complained of in the abdomen. On February 22nd, as the condition seemed urgent, Dr. Mackenzie, the resident assistant, tapped the patient at 3 A.M. with a small cannula and trocar, and five or six pints of bloody fluid were drawn off, with the effect of giving much temporary relief, but the man soon began to sink, and he died in a couple of days. The fluid drawn off was highly albuminous; this was due, in part at least, to the presence of blood, which was uniformly diffused through it at the time of its being drawn off; the blood-corpuscles settled down, after standing, into a dense layer, leaving the supernatant fluid of a straw-colour, with a specific gravity of 1.012. After fifty hours, the reaction to test-paper seemed neutral. In addition to blood-corpuscles, the microscope revealed cells three or four times the size of these, with large nuclei contained in them.

The inspection was made by Dr. Joseph Coats. The liver was found to present the most typical appearance of advanced cirrhosis, with contraction and deformity of the organ; it weighed two pounds eleven ounces. The spleen was moderately enlarged, the pulp firm, and the Malpighian bodies small and atrophied. The stomach presented appearances of catarrh. There was pretty general hyperæmia of the intestines, especially of the ileum and colon, with very marked slate-coloured pigmentation of Peyer's patches and of the general mucous membrane of the colon, with concentration of the pigment at particular spots in the latter, corresponding presumably with the solitary follicles. No hemorrhage was found anywhere except in the peritoneum, and no special source of this hemorrhage could be discovered, as the blood was quite diffused through the fluid, and no localised disorganisation was discoverable. There were a few flakes of lymph. There was no appearance of cancer. The kidneys were normal in size. On section, a certain amount of paleness could be noticed in the deeper layers of the cortical substance. Microscopic examination revealed well marked fatty degeneration of the renal epithelium, chiefly in the pyramids, and mostly towards their bases, but extending also into the cortical substance and involving the straight tubules alone. In a longitudinal section, the dark fatty straight tubules (pyramids of Ferrein) could be seen alternating with the transparent convoluted ones.

REMARKS BY DR. FINLAYSON.—This case of cirrhosis of the liver

seems worthy of record, on account of—1, the absence of any history of intemperance; 2, the bloody character of the dropsical effusion; 3, the peculiar nature and disposition of the intestinal congestion; and 4, the presence of tube casts in the non-albuminous urine.

1. Repeated inquiry of the patient and his wife left no doubt as to the truthfulness of the statements made regarding his habits. The man was not an abstainer, nor even, perhaps, rigidly abstemious, and he had been known to have taken too much drink on a rare occasion; but he was in no sense a drunkard, nor was he addicted to the habitual use of spirits in excess.

2. The bloody character of the ascitic fluid drawn off raised, at the time, the suspicion of cancerous disease, especially in the absence of any history of intemperance. The blood seems to have transuded without any distinct points of rupture. This character of the dropsical effusion, although certainly uncommon, does not seem to be altogether unknown. (See Frerichs' *Diseases of the Liver*, London, 1861, vol. ii, p. 43, and vol. i, p. 270.)

3. The marked congestion of the lower part of the intestinal tract (ileum and colon), and the slate-coloured pigmentation of the Peyerian patches, and of the mucous membrane of the whole of the colon, seem to afford some confirmation of the doctrine at which I lately arrived from a survey of the literature of the subject; namely, that obstruction of the portal circulation from cirrhosis of the liver tends especially to congestion of the large bowel; the more deeply pigmented solitary follicles in this case are also of interest in view of the opinion held by Dr. Parkes that dysenteric ulceration has often its beginning in these structures. (See my paper On the Relationship of Abscess of the Liver to Gastro-Intestinal Ulceration, *Glasgow Medical Journal*, February 1873, pp. 177-179.)

4. The presence of tube-casts in the non-albuminous urine in this case raises questions of much interest. This subject has of late been much under our notice at the Infirmary, in connection with the habitual appearance of tube-casts in cases of jaundice, quite apart from albuminuria, and also in connection with some other affections (see *BRITISH MEDICAL JOURNAL*, June 27th, 1874, p. 841). Indeed, it is possible that the tube-casts would have escaped notice if attention had not been specially directed to this subject at the time. It seemed impossible to account for the casts in this case on the ground of jaundice; indeed, the existence of jaundice was very doubtful, as the yellowness of the eyes may have been due to other causes; and the urine, instead of having the jaundiced tinge, presented the brilliant red appearance which has been often noticed in hepatic cases. If jaundice really were present, it was certainly slight; but the occurrence of casts in jaundiced urine seems directly related to the depth of the biliary colour. Hence some suspicion of renal disease was entertained during life, and some affection of the kidney was actually found after death; but further observations on the significance of tube-casts in non-albuminous urine are required, before we can safely assign to the above facts their proper connection.

SOUTH DEVON AND EAST CORNWALL HOSPITAL.

A CASE OF DIABETES MELLITUS TREATED WITH OPIUM.

(Under the care of Dr. CLAY.)

FOR the following report we are indebted to Mr. C. C. GILLES, M.B., C.M.

J. R., aged 16, a farm labourer, was admitted March 10th, suffering from diabetes mellitus. He complained of great debility and loss of flesh, constant thirst, and frequent passage of urine. There were no signs of phthisis present. His weight on admittance was 98½ lbs. During his first week in the hospital, the average amount of urine passed was 9½ pints; the specific gravity varied from 1044 to 1060, and it contained a large quantity of sugar—no albumen. He was put on diabetic diet, and ordered mineral acids and bark. After about a month on this treatment, he was put on half a grain of opium in pill, three times a day, together with the diabetic diet. The opium was gradually increased to one and a half grains three times a day, when it was decreased, and eventually left off. For about a fortnight of this time, the treatment had to be suspended, on account of an attack of ephemeria coming on. The patient remained on diabetic diet alone for about a week; but as this did not appear to agree with him, he was ordered one grain of opium three times a day, and mixed diet; as this did not agree with him as well as the diabetic diet alone did, he was ordered diabetic diet together with the opium. Under this plan of treatment he improved very much, and left the hospital on September 15th, to resume his occupation, having gained 19½ lbs. in weight, passing on the average eight pints eight ounces of urine less than he did when he was admitted, and there being a very great diminution in the amount of sugar.

REVIEWS AND NOTICES.

CLINICAL SURGERY: An Address delivered in the University of Glasgow. By GEORGE BUCHANAN, A.M., M.D., Professor of Clinical Surgery. Pp. 32. Glasgow: J. Maclehose. 1874.

DR. BUCHANAN'S address is an inaugural one. The professorship is a new foundation, and the University authorities have taken the opportunity to found a new chair, that of clinical surgery, with the object of attaching to their medical school a professor who should devote his time to the teaching of clinical surgery, to the exclusion of any other branch of medical science. It is to be presumed that the future occupants of this chair will be men who have gained experience as practical surgeons, and naturally their services will be much in request, both by the public and their professional brethren. It follows, therefore, that only a limited portion of their time will be available for teaching, and that will be concentrated on clinical work. In this respect, clinical teaching differs from the systematic teaching of most of the fundamental branches of medical science. Anatomy, physiology, chemistry, botany, and zoology, are best taught by men whose attention is not distracted by the anxieties of professional practice, and who have time to work out and think out the problems which are constantly springing up in the advancement of science. Their appropriate place is the laboratory and the study, and the facts which they deal with can be elucidated without any direct reference to the inroads of disease as seen in the living subject. Accordingly, for the professors of these branches to engage in medical practice would seriously interfere with their usefulness in investigating and teaching their several departments in science. But with clinical lecturers it is different. An extended practical experience in the treatment of disease is necessary to make their instruction of real value. Theoretical knowledge, however extensive, and by whatever means of study acquired, is of no essential use, unless it has been put to the test of experience—an experience gained by the practice of surgery both in public and in private.

The advantage, nay, even the necessity, of such a professorship is obvious; and the University of Glasgow could have made no worthier choice than that of the distinguished surgeon who now inaugurates the chair, giving as he does in this address, with all becoming simplicity and modesty, his credentials for the post by describing the improvements which it has been his good fortune to introduce into the various departments of surgical practice which we shall proceed to notice. First, however, let us quote from Dr. Buchanan's address the practical arrangements which are made for the teaching of clinical, as distinguished from theoretical surgery at this great Scotch school—arrangements which strike us as eminently practical where the end to be reached is to give the maximum number of students as much instruction as possible out of the minimum number of cases. There are three main difficulties in the way:—1. The limited time at the lecturer's disposal in which to make his diagnosis, and explain the case to the students; 2. The imperfect acquaintance which the students have with the case in particular and with the science of surgery in general, and the consequent difficulty they experience in understanding the lecturer and in profiting by his attempts to instruct them; 3. The number of students rendering it impossible to address them each individually, and impossible even for each of them to get access to the patient's bed, or to see the features of the case to which the professor is alluding. The first difficulty can only be got over by the professor himself. One man can find out more, and say more, about a given case in five minutes than another would in an hour; and we doubt not that the distinguished clinical teacher who is now professor at Glasgow is an adept in this most necessary part of his art; yet it is a serious difficulty for any one, however acute and experienced, and it has this further drawback—that it leads the professor to concentrate his attention on the rarest and most difficult—the interesting—cases, to the exclusion of those which are more familiar, and which will form almost exclusively the stock of his pupils' practice hereafter. One of the advantages of the apprenticeship system, to which Dr. Buchanan alludes only to denounce it, and of which, as he says, "the days are numbered", was, that it brought the student into familiarity with the very class of practice which he would afterwards manage for himself, instead of leading him so far into the *apices chirurgie*—the amputations, ligatures, excisions, etc.—as to forget the humbler ulcers, sprains, and eruptions, with which his future experience

* In passing, we would beg to enter our decided protest against this doctrine, as applied at any rate to anatomy. Chemistry, botany, and zoology, if the latter form any necessary part of medical education, are doubtless as well, or perhaps better, entrusted to men not in practice; but anatomy, the basis of all practical surgery, can only be properly taught to students preparing for practice by those who know the exigencies of practice, and the bearings of anatomical and physiological facts upon practice.

would be mainly concerned. One suggestion which Dr. Buchanan makes to remedy this defect we must notice, but only to deprecate any attempt to carry it into practice, *i.e.*, "an extension of our dispensary arrangements, by which senior students would be sent to attend poor people in their own houses, and in difficulty appeal for assistance to the dispensary staff." Surely we see enough of the mischiefs of careless and inefficient attendance on out-patients, without turning over the unfortunate clients of our dispensaries to youths who are confessedly ignorant of the principles of surgery, and who would be not only unfit to face a difficulty, but who still more would not know where the difficulty was. If the apprenticeship system is so worthless and so effectual as Dr. Buchanan represents, the only resource is to utilise those hospitals to which as yet no schools are attached, and to see that no student is admitted to examination without ample practical familiarity with the personal management of cases. The differences between house and hospital practice on which Dr. Buchanan remarks (page 16) are no doubt real, but they are of minor importance. A good hospital dresser or house-surgeon, with a knowledge of his work and a love of it, will in no long time make an excellent private practitioner, and easily acquire all the minor arts which distinguish house from hospital practice; but what can supply the want of all practical instruction? A man can no more be lectured into being a surgeon than into being a carpenter, and it is singular to see sometimes how poorly the best pupils and prizemen of the schools acquit themselves when brought face to face with any common call of practice. This is a matter which the authorities of our large schools would do well to look to. The second difficulty—that of making cases intelligible to those students who have little previous knowledge of the rudiments of their profession—is not explicitly handled in Dr. Buchanan's address; yet it is one which all clinical teachers must have painfully felt. It seems to us to be best met by some method of familiar examination, so as to see that the students really understand the terms used, and follow the professor's reasoning. Such methods of teaching are no doubt laborious and difficult for busy men to carry out, but they ensure that the class at any rate gathers something from the exposition, which a mere lecture or demonstration does not always do. To meet the third difficulty—the number of the class—Dr. Buchanan, after describing the ordinary clinical comments at the patient's bedside, or in the clinical lecture theatre after adjourning from the bedside, thus gives the heads of a plan, which is also, we believe, carried out at Edinburgh, and with much success.

"Inasmuch as all are not equally fortunate in getting near the bedside—though arrangements will be made for attaining that position in rotation—a different mode is adopted at the regular weekly lecture on clinical surgery, a plan to make the instruction equally available to all who are present in the theatre; that is, to bring the patients from the wards into the place of lecture. The patient is placed in a chair, or, if he be unable to walk, remains on the bed which has been brought from the ward. He is then examined just as formerly described, and removed to an adjoining apartment. A commentary is then given on the disease, and, frequently at the end or during this description, he is brought back to enable the surgeon to point out anything important which may have escaped notice. The patient being removed, the treatment is explained, and any operation necessary may be described in all its details without any reserve. If an urgent operation be required, it is performed at the end of the lecture; if not, it is done in the presence of the students on the next operating day. At a subsequent lecture, the students are informed of the result of the operation, and in the interval they have the opportunity of visiting the case in the ward. In this way, a clinical lecture is a condensed commentary on a particular example of disease which is presented before the students. It differs from the systematic lecture by concentrating into a focus all the essential points, and is in fact, as nearly as possible, a guide to the management of a similar case which may happen in the future practice of the hearers. By a series of these isolated lessons, the student gathers his general principles, and has his mind stored with vivid examples which he never forgets. It must be obvious, therefore, that clinical instruction is the most vital part of a student's education."

These arrangements are admirably adapted for their purpose—that of "clinical instruction"; but we must again and again protest that clinical instruction is far from being "the most vital part of a student's education". As in the teaching of anatomy, one hour that the student spends in accurately and painfully dissecting for himself is ten times more valuable to him than half-a-dozen hours spent in the lecture-room, though in the former he may only have succeeded in displaying (and that, perhaps, only imperfectly) one-tenth as much of the subject as has been glibly and perfectly demonstrated to him in the latter: so in the practical pursuit of surgery, two or three very simple cases, handled, dressed, annotated, and personally attended by the student himself, are worth twenty cases, however interesting or striking,

which he only looks at from an upper bench in the theatre, and hears the professor talk about. Dr. Buchanan does not omit to urge on his students the importance of dressing and note-taking; but, if we may be allowed to say so, we think his mind is on this occasion naturally a little too much filled with the new duties that he has undertaken, and he seems to give to formal instruction a preference over practical work, which, in our view, is the great vice and danger of the medical education of the present day. We have no objection to the method of appointing one special professor of clinical surgery, instead of the plan more commonly adopted in the London hospitals—for each surgeon to give clinical lectures in his turn—if it be thought that the clinical teaching gains thereby in method and definiteness; but we confess that we are surprised in Dr. Buchanan's address to see no mention of any other surgical teaching than that of the professors of theoretical and of clinical surgery. Admirable as those professors doubtless are, it is no slight thing to them to say, that the most efficient teachers of practical surgery ought to be the surgeons of the hospital, and of these we find no mention at all in this address, other than the two professors, and nothing at all of the rich instruction that can be obtained in assisting the house-surgeons and in the out-patient rooms. All the more striking cases, however, are to be brought under the notice of the students, and everything that is possible is to be done to give them the benefit of practical instruction, as is evident from the following.

"You will have abundant opportunity for clinical observation and instruction; you will lose no time in going from the hospital to your class-rooms; and, if during the day, anything of interest or importance should occur in the wards, which it would be for your advantage to see, a message can be sent in a few minutes to the University, and, at the close of your lecture-hour, you can go down to the hospital. I think it very likely that we shall adopt the plan of having two or three of the dressers alternately on duty to assist the house-surgeons in receiving and attending to the accident and emergency cases. In fact, we are now in a position to utilise to the utmost the facilities afforded by the proximity of the hospital."

Thus it appears that everything which experience and surgical capacity can do in the way of oral instruction will be done for the students, and that the limited number who can be accommodated as dressers will have some opportunity of doing something for themselves; but the very perfection of the plan for instruction shows the prevalent weakness of the surgical tuition of the day. Students flock more and more to a few favourite centres, and there is not, and cannot be, enough hospital material to afford even the tithe of them anything like adequate opportunities for doing things for themselves. In Edinburgh, it is said there are eight hundred students; at some of our great London schools attached to hospitals, the number of the beds is less than that of the students. How is it possible for men to dress, examine, and attend to cases for themselves under such circumstances?

The observations which Dr. Buchanan makes on various parts of surgery in which improvements have been introduced in modern times are both interesting in themselves, and show how large a share he has himself had in introducing or perfecting those improvements. Thus we learn (page 16) that Dr. Buchanan was the first person in Scotland on whom (he being then a first year's student) anaesthesia was produced by sulphuric ether; and in connection with this topic he relates a striking instance (page 17), in which a patient of his, on whom he was to have operated, fell down dead suddenly at the exact time fixed for the operation, which had been accidentally postponed—another illustration, in addition to some previously recorded, showing that some at least of the deaths attributed to chloroform may have been natural deaths accidentally coinciding with the administration of the anæsthetic. On page 25, we learn that the method of inflating the tympanum through the Eustachian tube, which the profession owes to Politzer of Vienna, who published it in 1862, had been discovered and practised by Dr. Buchanan two years previously, though not published. In tracheotomy for croup, Dr. Buchanan's services to surgery have been fully recognised; and at page 19 we have the following summary of his experience. "I have now operated more than forty times, and saved over one-third of the patients; and, when it is remembered that, in every case, medical treatment had proved of no avail, and death from suffocation was imminent, it must be conceded the results have been most gratifying." In lithotomy, again, Dr. Buchanan appears to have been active, though we are certainly surprised to hear that he only operated for the first time in 1866 (and apparently the operation was then a novelty in Scotland), and that all he can say about its use even at the present day is, "that others are adopting it in preference to lithotomy in suitable cases". No doubt this tardy adoption of a great advance in modern surgery is due to the opposition of Mr. Syme to any modification of the treatment of stone by lateral lithotomy. At the same time, Dr. Buchanan speaks of his namesake's operation with the

rectangular staff as a great advance on the old operation, which is by no means the verdict of southern surgeons.

We can only find space for one more extract, referring to an operation less known than perhaps it deserves to be.

"Cancer of the tongue most frequently begins at the side, caused by friction against a broken tooth, or the irritation produced by smoking a short pipe. Its progress is gradually to creep backwards, but it rarely crosses to the other side till it has invaded almost the whole of that in which it began. A case of this disease was admitted under my care in the Infirmary in May 1865, which gave me the opportunity of putting my idea into execution. I followed the first steps of Mr. Syme's proceeding. I then cleft the tongue from the tip to the hyoid bone, and removed the whole of the diseased half by a lateral cut. Examination of the excised half showed that my knife had gone quite beyond the disease. The patient made a good recovery, and is alive and well at the present day in Lochranza, in Arran; she is known to almost every one on the island. I consider that the plan of removing the lateral affected half, instead of the whole organ, which I have now frequently performed, is not only free from danger, but promises most satisfactory results."

In conclusion, we would say, that the whole address is well worth the study of clinical teachers, as embodying a very careful and efficient scheme of tuition. If we have thought it our duty to call attention to some of the defects of such tuition, it has been in no carping spirit, and certainly in no spirit of disrespect to Dr. Buchanan, who, we have no doubt, will carry out his work as successfully as the crowded condition of his school will permit.

THE ELEMENTS OF EMBRYOLOGY. By M. FOSTER, M.A., M.D., F.R.S., Fellow of Trinity College, Cambridge, and F. M. BALFOUR, B.A., Fellow of Trinity College, Cambridge. London: Macmillan. 1874.

THIS is the first instalment of a work which the authors propose to make a somewhat comprehensive account of the developmental phenomena of the animal kingdom. It contains a very detailed exposition of the structure of the embryo of the common fowl, from its earliest to its latest stages. The work is characterised by its thorough originality, and by the absolutely practical use to which its authors clearly intend that it shall be applied. Both of them have, as we know, most carefully followed the steps in the development of the chick by the application of the most approved methods of staining and section-cutting; the subject-matter is, therefore, one with which they are thoroughly familiar, and when they discuss or quote the opinions of Remak, His, Delacher, and Götte, it is not as mere compilers, but as competent critics—themselves contributors to the stock of embryological observations. This feature seems to us really to mark out Messrs. FOSTER's and BALFOUR's book from among the crowd of manuals and treatises on various sciences, which too often are the production of persons who are dexterous as *prêtis* writers, but have no living knowledge of the subject which they treat. Further, as to our second point: this book is not written to air the opinions, however valuable, of its authors among a select circle of embryologists, nor prepared solely to enlarge the scientific reputation of either of them. It has a far more valuable and worthy object. It is a practical guide for students; it may be placed in the hand of any tolerably well instructed second-year's man in a London school, or in our universities, with the certainty that, if the ordinary appliances of a histological laboratory be at his disposal, and if he follow the instructions and master the discussions here put forward, he cannot fail, by the expenditure of a very moderate amount of time and industry, to obtain a really solid knowledge of the modes of thought and the modes of experiment which belong to the science of embryology—a science which all biologists admit to be of first-rate importance, and of which, we must say, very few indeed in this country have any true first-hand knowledge.

In Chapter 1, the facts as to the structure of the hen's egg when laid, and its earlier history, from the time of its ripening in the ovary, are given, including the impregnation, yolk-cleavage, and first formation of the germinal disc. Then follows, in the second chapter, a brief summary of the whole history of incubation; the story to be told is rapidly sketched in an "argument". The subsequent six chapters are each devoted to a minute account of the changes occurring on the first day, second day, third day, and so on to the sixth, with which all the subsequent period is merged, since by this time the various organs have definitely taken up their positions and adult relations. In the last chapter, we have a special account of the development of the skull. It is calculated to induce the young student to make the chick his intro-

duction to that wonderful fascination of cranial morphology which has measured the strength, as it has elicited the best work, of successive generations of philosophical zoologists—Goethe and Oken, Owen and Carns, Huxley and Gegenbaur.

Without disparaging in the smallest degree the excellently clear descriptions of the text, we may say that, next to the seventy-one woodcuts, executed under constant supervision, and at no small expenditure of care on the authors' part, we value the Appendix, containing "Practical Instructions for studying the Development of the Chick". The recipes are as precise as those of a cookery-book, and are evidently meant to be put in practice in a straightforward and unpretentious way. One caution or word of advice we would add to what our authors have here so well said. He who will study the embryology of any organism must provide himself with two things, which may not at first seem necessary, and must use them in combination. The first thing is a practically unlimited supply of eggs at any desired stage of development; the second is time, free from all other engagements. These two things, brought into co-operation by large patience, make an embryologist.

We trust that this book will bear the fruit for which its authors look. It should greatly facilitate, wherever the English language is read, the study of development; it may be expected to bring into life numberless young embryologists, and to raise the nucleus of an English army of workers which shall fairly compete for honours with the German and Russian hosts now active and productive in that all-important study. It is, perhaps, worth pointing out, that this book is an exemplification of what is called the "practical spirit" of the English. There is no work of the kind in any continental language, and even the German student who wants a judicious statement of the facts of the chick's development, with directions to enable him to verify or reject the statements made, must turn to the "elements" of Messrs. Foster and Balfour.

One thing is urgently needed in connection with this book, and might readily be supplied by either author; it is a synonymy and glossary, carefully drawn up, so as to show what terms used by various German authors during the progress of the study have received identical or partially identical significations, and what may be the English equivalents adopted in the present volume.

SMALL-POX. By J. SUMMERFIELD CONRAD, M.D., Resident Physician at the Marine Hospital, and Professor of the Theory and Practice of Surgery, Washington University, Baltimore.

THE pamphlet which Dr. CONRAD has sent us is the result of experience gained during an epidemic of small-pox in Baltimore in the years 1871, 1872, and 1873. The total number of cases that came under his observation was 1246. Some of these presented appearances which, in the author's opinion, rendered them inadmissible into any of the classes into which small-pox is usually divided by most English writers on the subject, and he, therefore, describes them under a new class, to wit, "flat variola". These are cases in which the duration of life is about seven days, in which the rash is discrete, in which the papules become rapidly flat and umbilicated, showing in their centre a black spot at an unusually early period. A very characteristic feature in these cases is the absence of delirium. Dr. Conrad states that he can find no description of them by English authors, and accounts for this by observing that nearly all that came under his notice were among negroes, and not among whites. It appears to us, however, that he is simply describing a class of cases which were common enough in England during the last epidemic; cases usually included under malignant small-pox, and by some writers separated from the worst of all forms of this disease; viz., that which is characterised by an absence of vesicle, and by the presence of hæmorrhage in the skin, beneath the conjunctiva, and from the mucous tracts.

The mortality shown in Dr. Conrad's tables is very heavy, amounting to 42 per cent. of all the cases treated. Even when we find that, of the 1246 patients, 250 only had any satisfactory evidence of vaccination, it leaves a high death-rate. It is, however, interesting to observe that, among the properly vaccinated, the mortality was only 2 per cent., while among the unvaccinated 53 per cent. died. There was not a single death in the whole number treated where the patient had a good mark from vaccination done after puberty.

Dr. Conrad regrets that the different modes of treatment he adopted were attended with unsatisfactory results, but inclines to the belief that the internal administration of vinegar had some power in modifying the eruption. We may, perhaps, trace its beneficial effects to the fact, that it was used at the latter end of the epidemic, when the cases would be less severe and the mortality smaller than at its commencement.

REPORTS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, DECEMBER 1ST, 1874.

Sir W. JENNER, Bart., K.C.B., M.D., President, in the Chair.

Chondroma of the Lacrymal Gland.—Mr. BUTLIN showed a chondroma of the lacrymal gland. It had been removed by Mr. Vernon from a woman 28 years of age. It had been growing nine years, and five years ago a small portion of it had been removed. The eye protruded downwards and forwards, and the vision was impaired. An incision was made through the upper eyelid, and the tumour shelled out readily. The eye went back into its place. The vision is good, and there is no dryness of the eye. In histological structure the tumour was cartilaginous, and contained various cells, round and stellate. Trabeculae ran through it, containing remnants of the original structure of the gland.—The PRESIDENT asked if there were tears still.—Mr. HULKE said that the removal of these tumours did not interfere with the secretion. In two cases he had found dribbling of tears to be the consequence.

Osteoma of the Upper Jaw.—Mr. BUTLIN showed an osteoma of the superior maxilla. It was removed by Mr. Eddowes of Stamford from a man 39 years of age, who had been knocked down by a wooden bottle eighteen years ago. A hard swelling appeared at the seat of the injury. The left eye was pushed upwards and forwards by the growth. There was another osteoma of the alveolar process. On September 11th, he removed the left superior maxilla, and on the 30th, made a flap from the eyelid. Photographs were exhibited. The structure of the tumour was that of ordinary exostosis. The interest of this case lay in the long duration of the growth.—Mr. CHRISTOPHER HEATH asked if the hard part of the tumour had been microscopically examined. He thought it possible that the hard part might consist of odontine, or tooth-tissue.—Mr. BUTLIN answered that the tumour was not yet in a fit condition for the hard part to be subjected to microscopical examination.

Tumour of the Pia Mater.—Dr. CAYLEY exhibited a tumour of the cerebral pia mater. It was found in a woman who was a patient at the Middlesex Hospital. She had hemiplegia, with imperfect articulation. She had also cedema and albuminuria, with severe headache. She died in a few days. On the *post mortem* examination, a tumour of the size of a small orange was found near the corpus callosum. On the right side, a nodule protruded into the right hemisphere. It was loosely attached, and came away readily. The tumour was firm, yellowish-white in colour, and resembled brain-matter. On microscopic examination, it was found to consist of round and oval cells about the size of blood-corpuscles. A microscopic section was exhibited.

Popliteal Aneurism.—Mr. HULKE brought forward a case of popliteal aneurism cured by pressure. It had occurred in a short fat man, who presented himself at the Middlesex Hospital in April last with an aneurism in his ham about the size of an orange. By means of compression, the aneurism was solidified in a fortnight. A fortnight ago, the man died from an aortic aneurism, which ruptured into the pericardium. The aorta was much dilated.—In answer to a question from Mr. HOWARD MARSH, as to what method of compression was used in this case, Mr. HULKE said two tourniquets were used, one above the other below the tumour, and they were only relaxed at intervals.—The PRESIDENT asked what was the patient's age, and if there were only one aortic aneurism.—Mr. HULKE said that the man was 44 years of age; the other question he could not answer, as the necropsy was not made by him.

Excision of the Hip and Elbow.—Mr. W. ADAMS showed parts after resection of the hip- and elbow-joints. Three specimens of hip-cases were exhibited. The first was a case of caries and necrosis, in a girl aged 14, in which the head of the femur was destroyed. She had been ill seven years. The acetabulum was almost normal. The result was good. The next case was not so satisfactory. Here the head of the femur was not much affected; but the acetabulum was much diseased, and contained a sequestrum. The patient, a female aged 17, died ultimately of pelvic abscess, together with disease of the lungs and kidneys. The third well illustrated primary necrosis of the head of the femur, which contained several sequestra, one a large one. The pelvis was not much implicated. The patient went away improved. This series showed how the ultimate results of operation were associated with the seat and locality of the disease. Then followed a specimen from an elbow-excision. The patient was underfed and overworked in a foreign school, and had suffered for two years from disease in this joint. Good and perfect union followed the operation.—Mr. HOWARD MARSH said that Mr. Adams had not dealt with the most interesting part of the ques-

tion. Opinions were divided on the matter of excision of the hip; and large returns were not yet made. The cases were very difficult to follow. Limbs often remained useless.—Mr. CARR JACKSON said that there was frequently an atrophic condition of the bone at the point of section in these cases. A patient of his, a man aged 21, did well after an excision at the hip; but after some months, secondary abscesses formed, and he amputated at what had been the hip. The patient made a good recovery, but ultimately died of phthisis. He thought that atrophy often interfered with the utility of the limb, but that the operation was often performed in order to save life rather than to attempt to secure a useful limb.—Mr. C. HEATH said that he had seen some cases which had healed perfectly. When there was atrophy of the femur, they could not be called successful cases. The bone was very thin, on section, in cases which were ultimately amputated. Where there was osteomyelitis, amputation at the hip was to be preferred to excision, if the object were merely to save life, and especially if the limb were useless after excision.—The specimen was referred to the Morbid Growths Committee.

Aneurism of the Arch of the Aorta.—Dr. DOWSE exhibited an aneurism of the arch of the aorta, which he removed from a man aged 31, who was under his care in the Central London Sick Asylum at Highgate. The clinical signs and symptoms were hæmoptysis, angina, urgent dyspnoea, and dysphagia, but no dysphonia. There was dulness upon percussion over a widely increased cardiac area, with a well marked systolic thrill, felt upon palpation. A rough systolic grind was heard over all the valves, but more particularly over the arch of the aorta: there was also a diastolic aortic murmur. Upon opening the thorax, the pericardium was found to be adherent by old organisations to an ill-shaped mass, caused by a very considerable enlargement of the aorta, which took a course to the right, and in front of the right auricle. The aorta was completely changed by atheromatous disease, and the sac of the aneurism was formed by great thickening of the tunica adventitia. The valves were for the most part healthy, and the heart was neither markedly dilated nor hypertrophied.—Dr. Dowse also exhibited another aneurism of the arch of the aorta, which caused the patient's death by rupture into the pericardium. It was removed from a woman aged 31, who was admitted into the Central London Sick Asylum, Highgate, on the 5th of May, and died on the following day. During life, a pulsating tumour, of the size of an orange, was seen occupying the right half manubrium of the sternum. The clinical features of the case were wanting on account of the patient's sudden death. At the *post mortem* examination a large aneurism was found, which involved the ascending and transverse portions of the arch of the aorta. It was essentially sacciform in outline, and free from any fibrinous deposit in its true cavity. At what might be considered the upper wall of the arch a false aneurism commenced, extending superiorly to the top of the sternum, and for a considerable distance on each side. In this portion, formed by the outer coat of the artery, was a large mass of laminated fibrine, about the size of a cricket-ball, flattened from before backward. This blood-tumour was non-adherent to the sac, except at its upper part, so that the blood circulated freely around it.—Mr. BUTLIN said that the patient was once in St. Bartholomew's Hospital, and was kept on Tufnell's treatment for five months. During the first month there was no change, but after six weeks the aneurism grew less and harder, and seemed in a fair way to do well. The patient, however, one day said that she had had enough of starvation, and left the hospital. He would like to know how long after this it was that she came under Dr. Dowse's notice.—Dr. DOWSE could not tell. The sac was well filled with fibrine, and there was a free channel for the blood-current.—Dr. CAYLEY said it was not clear to him what the patient died of. Had there been rupture into the pericardium?—Dr. DOUGLAS POWELL made a remark as to the occurrence of hypertrophy of the left ventricle in aortic aneurism. In his experience he had seen little of it, and thought it was not essential.—Mr. MYERS said that he had found hypertrophy of the left ventricle always present in aortic aneurism in soldiers. The first specimen he thought aortic rather than cardiac aneurism. In cases of large aneurisms of the ascending aorta, diastolic *bruits* were found.—The PRESIDENT said the name of the first specimen was a mistake: it was an aneurism of the ascending aorta. He thought that hypertrophy of the left ventricle was not always found in aortic aneurism. In this respect his experience did not coincide with that of Dr. Myers. Hypertrophy was found in aneurisms where the aortic orifice was diminished. In his opinion, the hypertrophy was due rather to the general arterial condition than to the aneurism.

Rupture of the Trachea.—Mr. GODLEE exhibited a specimen of rupture of the trachea. It arose from an accident. The boy, seven years old, was run over by a cart-wheel, which also broke some of his ribs. At the *post mortem* examination, the right pleura was found to have many old adhesions. The rupture took place about an inch above the

bifurcation of the bronchi.—The PRESIDENT asked if there had been any cough.—Mr. GODLEE said the boy died too soon for them to observe that, or to make a physical examination.—Mr. HOWARD MARSH said that a case of rupture of the left bronchus had recently been brought into St. Bartholomew's Hospital. The pleura was full of air. Mr. THOS. SMITH punctured the thoracic wall, and a good current of air followed, giving the patient much relief. Death took place ten days afterwards. In this case there was also cutaneous emphysema.

Ovarian Cyst.—Mr. THORNTON showed an ovarian cyst which had been removed at the Samaritan Hospital. It was taken from a married woman aged 23, who had had no children. At first, it was thought to be an unilocular cyst; but Mr. Spencer Wells had seen it, and thought it to consist of several cysts. It was too large for a single cyst. The operation presented no difficulties; the fluid was watery, and the cyst-walls were easily removed. The ovary was so close that it had to be removed with the cyst. There was found one large cyst, with a number of smaller ones. Fibrous trabeculae often project into an unilocular tumour, and create the impression of the cyst being multilocular. Large vessels ramified over the tumour, but the arteries were not distributed on the plan of ovarian arteries. The ovary was enlarged, and the hylus was spread out over the base of the tumour. When an ovum was encapsuled in the broad ligament, an unilocular cyst resulted.

Calculi from Female Bladder.—Mr. CHRISTOPHER HEATH showed three calculi from the female bladder. They were from three different women. He had removed them by incision through the vagina. The first was one ounce in weight. It had three nuclei, which were massed together by phosphates. They had formed in a pouch in the bladder, and the symptoms came on after they were dislodged. The second was one ounce and a half in weight: of this no section had been made. The third was part of a stone: much phosphatic matter was broken off in removal. The first and third cases did well. In the second case, the phosphatic urine prevented the wound from healing by first intention. He preferred a free incision, as in small incisions the edges became bruised and did not heal well. He would not suggest vaginal incisions for young patients, but in adults with capacious vaginae it was the best plan.

MEDICAL SOCIETY OF LONDON.

MONDAY, NOVEMBER 30TH, 1874.

VICTOR DE MÉRIC, F.R.C.S., President, in the Chair.

Dislocation of Patella.—Mr. J. ASTLEY BLOXAM exhibited a boy, ten years old, having a dislocation of the patella, which had existed five years. There was no pain; only a slight feeling of weakness. The dislocation occurred every time the knee was flexed, reduction taking place with extension. The patient's family was generally affected with rickets.—Mr. WM. ADAMS remarked that the case was one of dislocation of the patella, accompanied with only slight knock-knee; this lesion being generally associated with a marked degree of knock-knee. Dislocation of the patella seldom caused synovitis among children; it was the result of a loose condition of the ligaments and the surrounding tissues. He remembered an instance of a young gentleman who had both patellae dislocated. He recommended the knees to be kept extended in leather splints for one or two years; the patient entirely recovered the use of his limbs.—Mr. DAVY knew no cases so difficult to manage as these. He related a case of a man, aged 40, on whom a splint was used for a whole year, and on its removal the deformity returned as badly as ever. Mr. Davy considered that some mode of appliance by which the action of opposing muscles could be equally balanced, was highly desirable.

Cystic Sarcoma of the Neck.—Mr. BLOXAM exhibited a woman, from whom he had removed the zygoma and styloid process in the extirpation of a cystic sarcoma. Nine years previously, Mr. Hulke had excised half the lower jaw for the same disease. During the operation, Mr. Bloxam had to tie the external carotid artery and the internal jugular vein, both of which were divided. He pointed out the peculiarity of the growth returning after such a lapse of time.—Mr. LEIBREICH remarked that the want of seclusion of the eye observable in this case was due to two causes—(1) the destruction of the seventh nerve, and the orbicularis muscle, the eye could only be protected by turning it upwards; (2) the destruction of the fifth nerve, causing loss of sensation of the conjuncture, followed by corneitis and ulceration. There was no doubt that cataract had formed. He considered that the eye should be completely closed by stitches, forming an artificial symblepharon as a means to prevent further destructive changes.—Mr. BLOXAM said cataract had formed, and extensive paralysis of the fifth and seventh nerve had taken place since the last operation.

Excision of the Knee-Joint.—Mr. HENRY SMITH showed a specimen

of excision of the knee-joint, remarkable for the fact that when first admitted the patient seemed to have little or nothing the matter with him; after awhile, he complained of great pain and starting of the limb, and Mr. Smith diagnosed ulceration of the cartilages of the knee-joint.

Excision of the Knee-Joint.—Mr. R. DAVY narrated seven cases of excision of the knee-joint operated on by him in the Westminster Hospital. In cases No. 4 and 7, sinuses existed. Necessarily, shortening of the limb occurred in every case; but all the patients could walk with the aid of a high-heeled boot, and the improvement in health and the reduction in deformity had been marked. The average stay in hospital of the patients was eighty-two days, contrasting favourably with the two hundred and six days' stay of other excision cases (*vide Holmes's System of Surgery*, vol. iii, page 822). The author found Esmarch's bandage a great boon in these operations. The transverse incision over the line of articulation was strongly enforced. The ends of the femur and tibia projecting (on forced flexion) like the muzzle of a double-barrelled gun, especial care was given to the posterior ligament of the knee-joint, as it acted as a hinge to the two bones. The author sliced off the ends of the bones until accuracy of adaptation resulted in a straight line. Sutures of stout silver wire are used, restrained by large shot or lead tubes. No dressings whatever were requisite, but to brush the wound over with weak solution of Condy's fluid or carbolic acid, and attend to the temperature of the ward and enforce surrounding cleanliness. The cases were illustrated by four of the children who were present; also by casts, splints, instruments, etc. Mr. Davy attributed the success which had attended the results to Esmarch's bloodless plan as adopted at the Westminster Hospital, to the simplicity of the after-treatment, and to the stern enforcement of maintained rest.

CAMBRIDGE PHILOSOPHICAL SOCIETY.

MONDAY, NOVEMBER 30TH, 1874.

G. M. HUMPHRY, M.D., F.R.S., in the Chair.

Right-Handedness.—A paper on Lopsided Generations, or Right-handedness, by W. AINSIE HOLLIS, M.D., was read by Professor HUMPHRY, in the absence of Dr. Hollis. The antiquity and universality of the preferential use of the right hand was shown by reference to the Biblical and other records, and to Egyptian, Assyrian, and other monuments, as well as to various members of the Semitic and Aryan groups of languages. All modern nations, with one or two questionable exceptions, are right-handed, and have words to signify "left-handed" corresponding with the French "gauche" and the Italian "mancino". It appears to be a peculiarity of the human race, even the apes using the right and left limbs indiscriminately, and is associated with the higher and more elaborate muscular actions of the limbs in man; and, there being no other structural difference between man and the lower animals to account for it, the cause of the peculiarity must be sought in that part of the system, viz., the brain, in which he excels other animals. The left side of the brain was stated to be the larger in man; and it, through decussation of the nerve-fibres, presides over the right side of the body, and seems from recent observations also to preside over the complex and delicate muscular actions upon which articulation depends. The preponderance of the left side of the brain—the lopsidedness of the organ—thus engendered by the preferential use of the right hand, by the movements in speech, and by much of subsidiary brain-work directly associated with speech, is not without its evil; and instances were adduced, including those of Johnson and Swift, in which the left side of the brain had suffered and paralysis of the right side of the body had been induced, apparently, as a consequence of this overwork. The inference was drawn that such result might have been avoided had a more equal duty been required of the two sides of the brain by a more equal use of the two limbs; and in these days of high pressure it is of especial importance to attend to such points, and by more equal education of the two sides of the body, to lead to a fairer distribution of work between the cerebral hemispheres.—Professor PAGET thought that more evidence should be adduced respecting the greater size of the left hemisphere of the brain, and of the statement that in cases of aphasia the left side of the brain is likely to be affected in right-handed persons, whereas in the left-handed it is the right side of the brain, which is more likely to be found diseased.—Mr. ANNINGSOON questioned whether lopsidedness was really a part of right-handedness, forasmuch as the left hand is employed not only as a helpmate to the right, but for many purposes in which the right hand is less efficacious.—Mr. CARVER thought that observations in the nursery showed that right-handedness was acquired rather than innate; children having commonly a propensity to use the left hand, which it required some difficulty to counteract.—Professor HUMPHRY said he believed an advantage gained

by preferential use of the right hand was a greater aptness and precision of movement requisite for delicate manipulations than could have been attained had both limbs been equally employed. Left-handed persons, being prevented by social custom from concentrating their attention on the left hand and being compelled to give a frequent preference to the right, are at some disadvantage in this respect. He could see no anatomical reason for the preference of the right limb, the slight advantage in circulation to the right arm through the innominate artery and vein applying, in nearly equal degree, to the right side of the brain. He agreed with Mr. Carver that right-handedness was much a matter of education, and followed from the multifarious single-handed offices which are associated with the higher mental endowments.

The Omentum in Man and Vertebrates.—Dr. WILSON made a communication on the disposition of the peritoneum in man and other vertebrata. He gave a brief account from his own dissections of the anatomy of the peritoneum, and more particularly of its omental sac in man and many mammals, reptiles, amphibians and fishes. He showed that in many of these the omental sac is divided into two parts—a gastro-hepatic and a gastro-colic part—by a constriction corresponding with the upper border of the stomach. This he first observed in the dissection of a narwhal, and had found it marked to a variable extent in man, most evident in a young hippopotamus, distinct in the rat and in the human fetus about the third month. In reptiles and amphibians, the omentum does not extend below the level of the stomach. There is, therefore, only a more or less complete representative of the gastro-hepatic part of the omental pouch of man. One or more of the hepatic lobes usually project into the gastro-hepatic part of the sac. In man, it is the lobulus Spigelii. He described the relation of the spleen to the omental pouch, and stated that his observations were, on the whole, in accordance with the old and commonly received view regarding the mode in which the colon is embraced by the two recurrent layers of the omentum which pass on to form the transverse meso-colon.—Professor HUMPHRY remarked on the thorough manner in which Dr. Wilson had investigated the anatomy of the omentum, which was of much interest with reference to the development of parts. The increasing size of the omental pouch in the higher animals and in man must also be taken in connection with the recent investigations of Dr. Klein, respecting the relations of the peritoneal cavity to the lymphatic system.

MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

WEDNESDAY, DECEMBER 2ND, 1874.

RUTHERFORD HALDANE, M.D., President, in the Chair.

Case Simulating Inguinal Hernia.—Mr. ANNANDALE showed a boy, aged 8, whose case had been supposed to be one of double inguinal hernia, along with distension of the abdomen. There was an impulse on coughing, and the scrotal tumours could be returned into the abdomen. By puncturing one tunica vaginalis with a trocar, about eighteen ounces of a serous fluid were withdrawn; the fluid came from the tunica vaginalis of the other side and from the abdominal cavity as well, proving that all three cavities were in communication with each other. The urine was scanty, and diuretics were of little avail. Mr. Annandale believed the case to be one of dropsy.

Excision of the Hip.—Mr. ANNANDALE showed a girl, the head of whose femur he had excised for hip-disease. The patient seemed to be making a good recovery, though the limb was not yet fit to use in walking.

Separation of the Heart.—Dr. LITTLEJOHN showed a heart, which, in a railway accident, had been severed at the base. The spinal column was also crushed, yet the skin over the injured parts was unbroken.

Pleurapneumonia in an Infant.—Dr. LITTLEJOHN showed the lungs from a child, aged three days. It was illegitimate, and had died suddenly. There was marked evidence of acute pleurapneumonia, and the greater part was condensed; yet the entire thoracic viscera floated freely in water. The infarctus of the kidney with uric acid was well marked, and exhibited to the Society.

Epithelioma of the Lower Lip.—Mr. ANNANDALE showed the parts removed in a case of epithelioma of the lower lip and jaw. He had divided the soft parts freely, and then divided the jaw at the symphysis, and finding the whole thickness of the jaw was not affected, he had removed merely the outer layer of the bone; he had then brought the edges of bone together again with wire sutures. Unfortunately, the patient died of bronchitis, but the wound was looking well.

Calculus of Female Bladder.—Mr. ANNANDALE showed a calculus, shaped like a pencil, which he had removed from the female bladder by forceps after dilating the urethra. It had no nucleus.

Modification of Catheter.—Mr. ANNANDALE showed a catheter with

a small piece of India-rubber tubing fastened to its end by string, the ends of the string being knotted so as to act instead of eyelet-holes. This is to be used in cases where it is necessary to tie in a catheter, which may not be provided with the ordinary eyelets. He believed it to be an original idea.—Dr. P. H. WATSON remarked that he had for long been in the habit of employing the mode of tying in a gum-elastic catheter described by Mr. Annandale. In addition to the use of this plan, he could recommend that the India-rubber tube should be long enough to pass over the bedside, so as to hang over a chamber-pot, with a few coils on the bed, so as to admit of movement on the patient's part. He also fixed a clip on the tube, by which the patient could relieve himself without rising or altering his position.

Excision of Bones of Foot.—Dr. WATSON showed the foot of a patient, from whom, in March 1874, he had removed the scaphoid, cuboid, three cuneiform bones, and base of the metatarsals, to illustrate the amount and kind of consolidation which occurs after this operation.

Instruments for Internal Urethrotomy.—Dr. WATSON showed two urethrotomes for internal urethrotomy, which he had recently had constructed in accordance with designs of his own. The instruments were essentially the urethra staff for external urethrotomy as employed by Mr. Syme, with a concealed knife of the size of the common tenotomy-knife closing into the thin portion of the staff and hinged at its base. A screw in the handle protruded the knife after the instrument was introduced, so that the withdrawal of the instrument divided the stricture from behind forwards. The first instrument, which was as large as a No. 4 catheter, had been constructed for him by M. Mathieu of Paris; the second, of smaller calibre, by Mr. Young of Edinburgh.

Ovarian Tumour.—Dr. THOMAS KEITH showed an ovarian tumour, which he had removed from a patient in the fifth month of pregnancy. It had been frequently tapped before; but the occurrence of pregnancy and the fragility of its walls led him to operate. He stated that he had now performed ovariectomy one hundred and ninety times, with a mortality during the last three years of less than 10 per cent.

Lodgment of False Teeth in Oesophagus.—Dr. SINCLAIR showed the tongue, pharynx, and part of the oesophagus of a patient, who had accidentally swallowed a set of three false teeth. They had lodged in the upper half of the oesophagus; and, after some manipulation, Dr. Sinclair extracted them. Fourteen hours afterwards, the patient died from severe hæmorrhage. The point from which the bleeding came was not discovered; but there was extensive laceration of the left aryteno-epiglottidean fold.

Cases of Suffocation.—Dr. LITTLEJOHN read an account of two cases of suffocation under suspicious circumstances, of which the following is an abstract. The body of a man was found lying on the public street about 1 A.M.; and it was soon ascertained that he had either fallen or been thrown from a window on the third storey, which was open. No light was seen in the room. On the police going upstairs, they found the occupants of the house in bed and unconscious of anything having occurred. A lodger was missing who slept in a bed-closet with a companion. This bed-closet communicated with the room, the window of which was open. The companion, on being roused, was confused, and stated that he knew nothing of what had become of deceased, and that both had retired to rest the previous night on good terms. An inspection of the room showed no disorder of the furniture, but several marks of blood close to the bed and on the floor between the bed and the window. In one of these lay a knife covered with blood. The glazed cover of the table was missing, and was found lying close to deceased in the street, while the looking-glass, which usually stood on the sill of the window, had been removed and placed on a chest against the wall. Deceased presented several wounds on the head; and at first it was supposed that he had been assaulted with the knife by his companion; and, to escape further violence, had leapt over the window. Dr. Joseph Bell, in the absence of Dr. Littlejohn, was summoned by the authorities to assist them in investigating this suspicious case. Dr. Bell carefully examined the supposed assailant, and found some spots of blood on his hands, and also a large number of spots of blood on the pillow, bolster, and sheet. These spots were peculiar, and Dr. Bell at once suspected that they were not due to fresh drawn blood, but rather to blood which had lodged in the air-passages, and had been violently ejected by coughing or sneezing, and he regarded it as highly probable that deceased was either phthisical and had been seized with hæmorrhage in the lungs, or else that an aneurism had burst into the throat or air-passages, and produced violent expulsive efforts; and that deceased, in his desire to get rid of the blood without soiling the furniture of the room, had sprung from bed, and, removing the looking-glass, had seized the table-cover to protect the muslin of the window sill. In order to vomit freely, deceased leant forward over the window, overbalanced himself, and fell to the ground, bearing the slippery table-cover with him. On dissection, deceased was found to have sustained fracture of

the skull and other severe internal injuries, such as a fall could alone account for. The wounds of the scalp were lacerated, and could not have been inflicted with the knife, which it was believed had fallen accidentally from the table into the blood when the table-cover was removed. What added to the interest of the case, was the fact that the accused (who was kept for some days in prison until all the circumstances were ascertained) had had a quarrel with deceased a few days previously, and had been requested by the landlady to leave. A reconciliation, however, had taken place, and ultimately deceased agreed to take the accused back again as his sleeping companion. The accused was a strong robust man, of quiet, rather sullen, temper; had been in Australia; and had recently been an inmate of a lunatic asylum. The second case was one of sudden death, where a wife was found dead beside her husband, who was unconscious of any movement or struggle. The previous day she had complained of sore-throat, and late at night some pus had been discharged, to her great relief. A doctor saw her shortly after, and prescribed some simple remedies. He was naturally surprised when he was summoned at seven o'clock next morning and found her dead. On dissection, both tonsils were found swollen and infiltrated with pus. The trachea was filled with purulent matter, and the lungs and heart presented the usual appearances characteristic of obstructed respiration. Dr. Littlejohn, in conclusion, contrasted these cases, and showed how variable were the symptoms in cases of asphyxia, according as the asphyxiating agent acted quickly or slowly.

Case presenting Symptoms of Renal Calculus.—Mr. ANNANDALE related a case, in which aggravated symptoms of renal calculus had been cured or relieved by an exploratory incision. No calculus had been discovered. [The report of this case was published in the JOURNAL of December 19th.]

MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS IN IRELAND.

WEDNESDAY, NOVEMBER 18, 1874.

JAMES F. DUNCAN, M.D., President, in the Chair.

President's Address.—The President delivered an inaugural address. The Public Health (Ireland) Act, 1874, he characterised as a measure which, if properly and effectively administered, was likely to prove one of the most beneficial pieces of legislation ever introduced into Ireland. The State had only recently concerned itself with the great subject of public health. From the present Act, he looked for climatic changes in many districts of the country; a marked improvement in the sanitary conditions of our cities and towns; a beneficial effect on the habits and morals of the people, and an elevating influence on the future prospects and position of the medical profession. It was possible that the Act might be rendered inoperative by the ignorance and apathy of some, or the open hostility of others; but the danger was to be averted by the members of the medical profession throwing their energies heartily into the cause, giving a right tone to public opinion on the subject, and showing, as opportunity enabled them, the various important advantages—personal, social, moral, and commercial—that are sure to follow from proper care being taken of everything bearing on the health of the community. One of the greatest errors to be combated was the notion that sanitary measures were necessary only in times of threatened epidemics, or of the prevalence of the more dangerous zymotic diseases. Great delicacy and tact would be required in dealing with sanitation in the face of the prejudices of the lower orders, and even of the rate-paying classes. The President then considered at some length the text in the epistle of St. James, on which the "Peculiar People" rely in their treatment of the sick. He showed that the passage (St. James v, 14 and 15) was not to be interpreted as prohibiting the use of ordinary rational means to restore the sick, but that God addressed us as reasoning creatures, and took it for granted that ordinary means would be taken as a necessary condition to His answering prayer. As to the other point, "and the prayer of faith shall save him", this promise meant that, if it be for the sick man's good as well as for the Divine glory, God would restore him to health in answer to the prayers of His people, but not otherwise. The reduction of the question of the efficacy of prayer to a crucial test was as absurd and unphilosophical as it was unscriptural. The President, in the closing passages of his address, alluded to the retirement of Professor Apjohn from the chair of Chemistry in the University of Dublin.

Cheyne-Stokes' Respiration.—Dr. HAWTREY BENSON detailed a case in which this peculiar form of respiration had been a prominent symptom. The patient, a gentleman aged 45, a year ago had three sharp attacks of acute bronchitis. These were followed by repeated attacks of spasmodic asthma, and finally by a group of cerebral symptoms, including temporary loss of memory, mental confusion, giddiness,

headache, thickness of speech, tingling sensations in the extremities, and incomplete left hemiplegia. The hypertrophied heart now commenced to fail, and the Cheyne-Stokes' respiration appeared. The phenomenon lasted twenty-seven days, until within a few hours of the patient's death. Unfortunately, there was no *post mortem* examination.—Dr. HENRY KENNEDY had arrived at the conclusion that this peculiar symptom was more or less connected with the nervous system generally, rather than with any particular organ in the chest. The change in the respiratory characters during sleep, the cerebral breathing in fever, and the variable respiration of hydrocephalus, were facts which pointed in the same direction.

DUBLIN OBSTETRICAL SOCIETY.

SATURDAY, NOVEMBER 21ST, 1874.

EVERY KENNEDY, M.D., President, in the Chair.

Report of the Thirty-sixth Session.—Dr. J. R. KIRKPATRICK, honorary secretary, read the annual report, from which it appeared that the number of members was now a hundred and sixty, including twelve honorary members. The financial statement was extremely satisfactory, for, whereas there was a small deficit at the beginning of the past session, there was now a balance in hand of £28 18s. 8d.—Dr. T. MORE MADDEN moved and Dr. GRIMSHAW seconded the adoption of the report. The motion was carried unanimously.

President's Address.—Dr. EVERY KENNEDY delivered an address, choosing for his subject "Biology, in its Relations to Disease". He pointed out how deplorable it was that men devoted to the exploration of science—especially the science of geology—should have their equanimity disturbed by considering the possible influences which the elucidation of truth might exercise upon particular schools of religious thought. God is a God of all truth, and shrinks from no exposition of His own works. The propounder is no part of the discovery, neither is his sect his creed. On the other hand, scientific men should not be induced to tread rashly upon sacred ground, or to provoke attacks upon the various sciences. Free investigation in nature and science may be regarded as the obvious duty of man. The influence exercised by the laws of evolution, and "natural selection", in resisting the decadence of the vital powers, formed the groundwork of the remainder of the President's address. The ill results in scrofula and gout arising from the neglect of hereditary selection, were next commented on. The concluding portion of the address contained several most interesting illustrations of the action of "ideogenous molecules" in the human brain, in accordance with Professor Huxley's statement, that "each sensory impression leaves behind a record in the structure of the brain, which is competent, under certain conditions, to reproduce, in a fainter condition, the state of consciousness which corresponds with that sensory impression; and that it is these ideogenous molecules which are the physical basis of memory". The President's illustrations went to show that each repetition of the sensient impression renders more permanent, and more easily summoned, the idea, until it becomes almost (so to speak) omnipresent. Lastly, the law of instinct might be explained by the application of the principle of hereditary influence, and in this field of investigation we were often aided by abnormal experience or diseased action.

Election of Officers.—The President announced that the following members have been chosen by ballot as officers of the society for the session 1874-75. *President:* Lombe Atthill, M.D. *Vice-Presidents:* Thomas Darby, F.R.C.S.I., and John Cronyn, F.R.C.S.I. *Committee:* Fleetwood Churchill, M.D., John Denham, M.D., George Johnston, M.D., George H. Kidd, M.D., Alfred H. McClinckock, M.D. *Treasurer:* H. S. Halahan, L.K.Q.C.P. *Honorary Secretary:* J. Rutherford Kirkpatrick, M.B.

Votes of Thanks.—The chair having been taken by Dr. Atthill, the incoming president, a vote of thanks to Dr. Kennedy, the retiring president, was proposed by Dr. Kidd, seconded by Dr. Denham, and unanimously carried. Dr. Kennedy returned thanks. A vote of thanks to the visitors, moved by Dr. H. Kennedy, seconded by Dr. Mac Swiney, and carried, was responded to by the respective Presidents of the Colleges of Physicians and Surgeons, the Governor of the Apothecaries' Hall, and Mr. A. M. Sullivan, M.P. Several clergymen, including the Dean of the Chapel Royal, Dublin Castle, and the Dean of St. Patrick's Cathedral, were also among the visitors.

AN examination of Surgeons in the Royal Navy, who are eligible and who may be desirous of qualifying for the rank of Staff-Surgeon (second-class), will be held at the Royal Naval Hospitals at Haslar and Plymouth on Thursday.

BRITISH MEDICAL ASSOCIATION: SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, JANUARY 2ND, 1875.

REGISTRATION OF BIRTHS AND DEATHS.

ON January 1st came into operation the Registration Act of last session, which passed on August 7th. The law of registration is not very materially altered under the new Act; but it may be useful to notice a few of the modifications which have been made in the mutual obligations of the public, the registrar, medical men, coroners, and others more indirectly concerned in registration.

After January 1st, in the case of every child born alive, and of every death that occurs, it will be the duty of one of those persons who are specified as legal informants under the new Act to attend at the recognised office of the registrar, to give the necessary information respecting the birth or death, and to sign the register. Under the old Act, the registrar could be required to attend at the house in which the birth or death had taken place for the purpose of registering. Now, if an informant desire the attendance of the registrar at his house, or at the house in which the birth or death took place, for the purpose of registering, he must send a written requisition to that effect to the registrar, who, on attendance to register, will be entitled to a fee of one shilling. The number of legally qualified informants for both births and deaths is, under the new Act, considerably increased; and, in order to obviate as far as possible the hardship of informants having to travel long distances to attend at the registrar's office, the appointment of registration stations in districts of large area, at which the registrars will be obliged to attend at stated times, has been sanctioned and required. These stations, and the hours for the registrars' attendance thereat, have been proposed by the local registrars, approved by the superintendent registrars, and sanctioned by the Registrar-General. The arrangements as to these stations, and the times of the registrar's attendances thereat, will be locally published.

The registration of births is now for the first time made compulsory. An informant is bound, under a penalty of forty shillings, to give information of a birth, and to sign the register within forty-two days; and, after the expiration of that period, in case of non-registry, the registrar may, by notice in writing, require any of the persons constituted as qualified informants by the Act to attend personally at the registrar's office to register the birth. After the expiration of three months, and at any time within twelve months of the birth, it may be registered in the presence of the superintendent registrar, as well as of the registrar, both of whom will have to sign the entry. After the expiration of twelve months, no birth can be registered except on the written authority of the Registrar-General, the fact of such authority being entered in the register. These are, however, additional facilities for registration, as, under the old Acts, no entry of a birth could be made after six months from the date of the birth.

A provision is also made under the new Act which will afford considerable convenience to the public in registering births. In the case of a person whose duty it is to give information concerning a birth, and who moves out of the district in which the birth takes place previously to its registration, the information can be given to the registrar into

whose district the informant has removed. The particulars relating to such births are to be entered upon forms provided for the purpose, attested by the registrar to whom the information is given, and then transmitted to the registrar of the district in which the birth occurred for entry in his birth register-book.

The new Act gives additional facilities for adding or altering the Christian name or names of a child after the child has been registered either with or without name. According to the Act lately in force, such alteration or addition could only be made within six months of registration, and on the production of a baptismal certificate. With regard, however, to children born after the 1st of January, the time wherein this alteration or addition of name can be effected is extended to twelve months, and registrars are authorised to register such alteration or addition on the production of a "certificate of naming", signed by "the father, mother, or guardian of the child, or other person procuring the name of the child to be given or altered", as well as on the production of the certificate of baptism, as formerly. This enables persons who do not practise the baptismal rite to add after registration, or to alter, the name of a child.

We may mention one more alteration which affects the birth-register. No mother of an illegitimate child born after the 1st of January can have the name of its putative father inserted in the register at her sole request; this information can only in future be inserted "at the joint request of the mother, and of the person acknowledging himself to be the father of such child, and such person shall, in such case, sign the register, together with the mother".

With regard to the registration of deaths under the old Act, it was more or less compulsory, as any minister who officiated at the burial of a person whose death was then unregistered incurred a penalty if he did not give notice of the fact to the registrar of the district in which the death occurred. Moreover, there is a very wide-spread popular impression that a body cannot be buried unless the death has been registered, and a certificate of registry produced to the officiating minister. The new Act will, however, impose upon the public, with regard to the registration of deaths as well as of births, much more definite responsibilities. As before mentioned, the number of persons legally qualified, and who may be required to give information of, and to register, deaths is largely increased. One of these persons must, within *five days* of the death, take one of the three following courses of action—either go to the registrar and give the necessary information, produce the medical certificate, and sign the register; or send to the registrar a written notice of the death, accompanied by the proper medical certificate; or send a written requisition to the registrar to attend at the house where the death has occurred, or at the residence of the informant, to register the death, in which case the registrar will be entitled to a fee of one shilling, as in the case of registering births under similar circumstances. When a written notice of a death, accompanied by a medical certificate, is received by a registrar, he is required to give a "certificate of notification of the death", which will as much entitle the officiating minister to bury the body as the production of a "certificate of registration": in these cases the actual registration of the death will have to be effected by one of the qualified informants within *fourteen days* of the death. This power of delaying the registration of a death for fourteen days appears to be fraught with objection from a sanitary and statistical point of view. If any considerable number of deaths be not registered until fourteen days after they have occurred, the weekly returns of registered deaths will lose much of their value to the health-officer and the statist; as, however, it will give the public almost as much trouble to obtain a notification from the registrar as to go and register the death, which must be done afterwards, we do not anticipate that any considerable delay will take place in the registration of deaths in consequence of this modification under the new Act. After the expiration of fourteen days, if a death be still unregistered, a registrar may

issue a requisition, calling upon any duly qualified informant to attend at his office or station to give the necessary information and to sign the register. The penalty for not giving information in the first instance, or for not attending to such requisition, is forty shillings.

The regulations under the new Act as to the burial of still-born children are much more stringent than formerly, and will, doubtless, serve as a salutary check upon infanticide. Any person who wilfully buries, or causes to be buried as still-born, the body of any child who was born alive, incurs a penalty of £10. Moreover, the burial of a still-born child in any burial ground after the 1st January is forbidden, without the production either of a written certificate that such child was not born alive, signed by a registered medical practitioner who "was in attendance at the birth, or has examined the body of such child"; or a declaration, signed by a person who under the Act would have been legally qualified to have acted as informant at the registry of the birth, had the child been born alive, to the effect that the child was not born alive, and that "there was no registered medical practitioner present at the birth, or that his certificate cannot be obtained"; or, if there have been an inquest, an order from the coroner.

The new Act requires all registered medical practitioners to give a certificate of the cause of the death, according to "the best of their knowledge or belief", of any person upon whom they may have been in attendance during their last illness. This certificate must be signed and given to "some person required by this Act to give information concerning the death", and the refusal to give such certificate will render a registered medical practitioner liable to a penalty of forty shillings. As the new form of medical certificate was recently described in these columns, we need only again state here that it is entirely free from all the objections which have often been urged against the form lately in use. The name of the certifying medical practitioner will in future be entered in the death-register, which will not only add considerable value to the certification, but act as a check upon the issue of certificates by unqualified practitioners.

With regard to the registration of deaths, respecting which inquiries have been held, the most useful modification made by the new Act is a clause which renders it incumbent on the coroner to send to the registrar a "certificate of the finding of the jury", commonly called a coroner's information paper, within five days of the conclusion of the inquest. This will in future prevent the frequent delay which has hitherto occurred in the registration of inquest cases. Coroners have in many instances been in the habit of forwarding their information papers to the registrars in batches, once in three months, which seriously interfered with the value of periodical returns of registered deaths, whether weekly or monthly.

The only other clause of the new Act which it is necessary or desirable here to mention, is the one which regulates the furnishing, for sanitary purposes, particulars relating to deaths registered. The Act says that "every registrar, when and as required by a sanitary authority, as defined by the Public Health Act (1872), shall transmit by post or otherwise a return certified under the hand of such registrar to be a true return of such of the particulars registered by him concerning any death as may be specified in the requisition of the sanitary authority". The Act goes on to specify that for such return the registrar "shall be entitled to a fee of twopence, and to a further fee of twopence for every death entered in such return, which fee shall be paid by the authority requiring the return". This clause will put an end to a very anomalous state of things as regards these returns of deaths to sanitary authorities. Registrars were not bound to furnish such returns at all under the old Act, and both the furnishing of the returns and the price to be paid for the service was a matter of private arrangement between the registrar and the sanitary authority. It is easy to imagine that the result was not in all cases satisfactory.

It is much to be regretted that the Act, so far as it related to the

furnishing of these returns for sanitary purposes, was not made operative throughout the metropolitan area, which area was not dealt with by the Public Health Act (1872). In this way the difficulty which has been placed by the London vestries in the way of remunerating the metropolitan registrars for furnishing weekly returns of deaths for the use of medical officers of health, would have been obviated.

On the whole, the alterations and modifications in the law of registration which came into force on the 1st of January, although not of a sweeping character, and although not including some of the improvements which have from time to time been suggested and urged, may be regarded as satisfactory alike to the public and the registrar. Perhaps the most regrettable feature in the result of the new Act is, that no alteration has been made in the schedule of the birth and death registers, whereby additional facts, important alike to the interests of sanitary progress and State medicine, might have been recorded.

STATE MEDICINE QUALIFICATIONS.

WE are being deluged with announcements of projects of examination on State Medicine and Public Health. Some of these examinations are to be conducted by universities, having the prescriptive right to grant degrees or certificates of qualification in any department of learning or science which can be taught or studied in a university. But it appears, that such examinations are also proposed by various licensing bodies, consisting solely of medical practitioners, each of which bodies, being a rival for the grant of medical diplomas, very naturally desires to add to its programme any and every subject which may induce its candidate licentiates to complete their preparation for office as well as for general practice. Thus, subjects which are by no means essential to the efficient and successful practice of any therapeutic branch of our art, are, it seems, to be introduced into the medical curriculum of each purely professional body.

Now, it is not to the point to argue that public and private medicine are inseparable, and that subjects of preventive and legal medicine can be successfully studied only by those who are thoroughly qualified in the therapeutic, as well as in the scientific principles, of curative medicine. All this may be granted, without claiming—as many of our practitioner friends claim—that no special qualification for public office shall be granted to any one, except as part of a general scheme of qualification to be required of all practitioners. Still less does it justify the ridiculous demand, that every one aspiring to public office shall accomplish, within the period legally required for the attainment of an ordinary qualification for practice, a knowledge of all those additional subjects which may be required for special public offices. Yet this is virtually the demand which every College of Physicians, every College of Surgeons, and every Society of Apothecaries or general practitioners, is about to make, and which some have already made.

To what extent these rival claims of competing licensing bodies may be supplied, or perhaps superseded, by any conjoint scheme, we do not pretend to say, nor can any of these bodies say, until the said conjoint scheme is completed and in operation.

The last novelty is an announcement of the Society of Apothecaries, that it is about to institute, of itself, examinations in Public Health, so that candidates passing these examinations may be enabled to offer evidence of their fitness to hold office, more valid than that of so-called "testimonials". Now, once admit that each licensing body may, by itself, accomplish everything which may be required by all of them jointly or separately; and we see no reason why the Society of Apothecaries, or any college of practitioners, should be excluded from the general competition for special qualifications; but, to admit so much, is to throw overboard the whole of the original work of the General Medical Council, and of our Committee, on a "State Medicine Qualification, and to allow that the desideratum may be safely left to the working of the ordinary political principle of demand and supply". The late efforts of the universities are not altogether open to criticisms,

which are inevitable when the matter is taken up by individual medical corporations.

The report of our State Medicine Qualification Committee (see BRITISH MEDICAL JOURNAL, August 22nd, 1874) has not received from the educational leaders of the profession, we are sure, that consideration to which it was fairly entitled; and we hold that this Committee has a just ground of complaint. No properly selected deliberative body can be expected to devote, without some moral encouragement, earnest, laborious, and continuous efforts to the settlement of a question, which may be shelved by official indifference or prejudice, or may be frittered away by a kind of *reductio ad absurdum*, among a number of conflicting corporations.

We may have more to say about the recent proposals of the University of Cambridge; and there is also something pending in that of London, to which we may call attention.

RAILWAY PATHOLOGY.

THE case of Maldon v. the Great Northern Railway Company is one of a class which is familiar to those engaged in railway cases. Great and continuing nervous disorder suggests to the pessimist the probability of local lesions destined to end in nervous paralysis. The absence of positive indications of such lesions encourages the optimist to take a hopeful view. The real truth is, that neither side really understands the nature of the case; and they know it. We do not say that, in the present state of neurotic pathology, an adequate explanation is to be found by the most impartial critic. But we think that, were the "railway" element disregarded, the affinities of such cases to an important clinical group might be discovered. This comparison might, indeed we believe does, throw some light upon a confessedly dark diagnostic and therapeutical spot.

There is not a single symptom or sign in this, and the many similar cases, which does not appear in Dr. Golding Bird's category of those endured by persons suffering from oxaluria, with excess of urea in the urine. We are not concerned with the accuracy or adequacy of his theoretical explanation of this condition; all we contend for is, that such a condition of the urine is often to be found, in private practice, clinically associated with a group of symptoms such as it was admitted that Mr. Maldon presents. The combination of such symptoms, with the characteristic urine, has occurred on more than one occasion within our own knowledge in railway cases. We know that in such cases the patient, apart from any question of compensation, honestly entertains the most exaggerated apprehensions. He fears paralysis, insanity, consumption, etc. His medical attendant, too, should he be ignorant of his patient's real condition, may not be indisposed to fear the worst. But in private practice these apprehensions are not realised; nor are they in railway cases. Correct, though often tardy, recognition of the nature of the disorder is followed by appropriate treatment, and pretty certain often speedy cure. Unrecognised, these cases are often most inappropriately treated. Anxiety, too, is an undoubted factor in this form of oxaluria; hence it is often a most sound opinion, though the explanation is unknown to those who propound it, that the claimant's mind being relieved from the anxiety of an impending trial, he will speedily recover.

We hope that, attention having been called to the point, it may be fully investigated by those whose duty it is to make themselves specially familiar with "Railway" pathology. We venture to predict that, when this has been done, some of the pathological and diagnostic speculations which were aired in Maldon's case, will not be again propounded by men of admitted eminence. For, even should the urine in any particular case not present the peculiarities alluded to, the remaining symptoms being such as are known to disappear completely, the probabilities of recovery and the improbability of organic lesion are much greater than they are commonly represented to be in a court of law.

MR. LENNOX BROWNE, Surgeon to the Royal Society of Musicians, has been appointed also Aural Surgeon to the Society, in place of the late Dr. Peter Allen.

THE Custom House returns show that, in the financial year 1873-74, there were 14,992 lbs. of chloral hydrate imported into the United Kingdom.

AT the next meeting of the Pathological Society of London (January 5th), it will be proposed to alter the hour of meeting from eight to half-past eight in the evening.

WE learn that the Registrar-General purposes during the ensuing year to include the suburban metropolitan postal districts in his weekly bills of mortality, which will therefore henceforth include a population of upwards of four million souls.

WE are informed that Sir Henry Thompson has resigned the office of Surgeon at University College Hospital. This early retirement of Sir Henry Thompson from the public duties of the hospital is, we believe, due to the pressure of private professional work, which will be the more severely felt now, owing to the untimely death of the late Mr. John Foster, who had for many years rendered him great assistance.

THAMES VALLEY BRANCH OF THE BRITISH MEDICAL ASSOCIATION. WE see with pleasure that it is proposed to form a Thames Valley Branch of the British Medical Association, in order to bring into scientific relation and social union the medical practitioners of a large number of towns and villages for whom the Metropolitan Counties and South-Eastern Branches fail to offer inducements and facilities. The towns included necessarily differ, by their relations to the Thames, as to their county; but they form a natural grouping, easily accessible one with the other by railway, which it is desirable to bring into accord for all the purposes for which the Association exists. Dr. Atkinson, of Silverdale, Kingston, has kindly undertaken the duties of Honorary Secretary *pro tem*. An early meeting will be called to inaugurate the Branch, if a sufficient number of gentlemen signify their willingness to join. Dr. Langdon Down, of Normansfield, Hampton Wick, is taking an active part in promoting the movement. We believe it to be a very desirable and useful one, and we hope that the new Branch will flourish.

MILITARY HONOURS TO ARMY AND NAVY MEDICAL OFFICERS. A CORRESPONDENT, whose letter we publish in another column, calls attention to the fact that the grant of military honours to the medical officers of the army and navy was the immediate result of a series of memorials and representations to the government by the officers and branches of the British Medical Association, and especially to Lord John Russell in 1850; who, soon after the presentation of a memorial from the general meeting of the Association at Hull in that year, granted the claim set forth in the documents laid before them.

SOCIAL TIPLING.

"I NEVER was the worse for liquor in my life", is the frequent and honestly meant declaration with which the physician is often met in the frequent cases in which it is clear to him that polite tipping is the source of fatal disease. At the Medical Society of London lately, in the course of an interesting discussion on a frequent form of dyspepsia and brain-disease, Dr. Theodore Williams observed that most of these cases occurred among people with tipping habits, whose practice it was to take stimulants between meals whenever they felt what they call "low". The result was bad in two ways. Firstly, the alcohol introduced into the stomach caused a large secretion of gastric juice, which, having no food to act on, irritated the mucous membrane and gave rise to flatulence, distending the stomach, and thereby disordering the heart's movements; hence, palpitation and irregular supply of blood to the brain, with its accompanying symptoms. Secondly, the waste of gastric juice prevented a proper amount from being forthcom-

ing at meals; the food was only partially digested, and escaped assimilation; hence, starvation of the blood and consequent anæmic symptoms. The treatment most successful, therefore, in these cases, was a careful combination of food with stimulants, and a reduction of the latter as much as possible. Dr. Routh agreed with the author (Dr. Thorowgood) as to the common occurrence of these cases among women. Chronic alcoholism he noticed chiefly among matrons, and he treated it by two methods: the hankering after stimulants he satisfied by a harmless one in the form of assafœtida or valerian; or he gave raw beef-juice, prepared by rubbing beef through a sieve, and flavouring it with a little celery. Three claret-glasses a day of this juice were given, and it allayed the desire for spirits.

HOSPITAL OUT-PATIENTS.

THE report of the St. Bartholomew's Hospital, Chatham, contains the following satisfactory paragraph.

The patients steadily increase in number, causing some anxiety; for whilst there is every desire on the part of the trustees to afford aid to every person in want of hospital assistance, there is the fear lest the independence of the people be sapped by gratuitous benefits proffered them, and the trustees are of opinion that one of two courses will have to be pursued, viz., to institute a vigorous examination into the circumstances of every applicant, or to regard subscriptions from working men in the light of provident payment. Should the latter course be adopted, the medical profession could no longer be asked to render honorary services, and an increase in the amount of subscriptions will be necessary to enable the trustees to meet the increased expenditure due to payment for medical services.

THE DANGERS OF CHLOROFORM.

THE crusade against "chloroform-deaths" which we have carried on during the last two years, has had the effect of bringing very prominently into notice the superior safety of ether, and, for short operations, of nitrous oxide. We had, indeed, the satisfaction of witnessing an "ether-revival". The ether-revival has, however, not extended either so widely or so deeply as it should have done, or as it will, we believe, yet do. It is, indeed, necessary to hit the same nail on the head many times and oft before it is well driven in. We have had the pain of chronicling recently two fatal cases of death from chloroform and from bichloride of methylene, which we believe to be a yet more noxious agent. We observe the record of two further chloroform-deaths abroad; and next week we shall republish an analysis of the ether discussion which was last year carried on for many months in our columns, as it will, we believe, be desirable to renew the influence of the articles and letters which we then published. We are very glad to see that some of our medical contemporaries are now disposed to give their aid in the matter, and we hope that a chloroform discussion may be raised at some of the principal societies in London and elsewhere.

PRIZES OF THE ROYAL COLLEGE OF SURGEONS.

As showing how little ambition influences the profession, or rather the members of the Royal College of Surgeons, who only are allowed to compete for the Collegial Triennial and Jacksonian Prizes, in the gift of the College, we understand that only two essays have been sent in for the latter, and that, too, on such an interesting, important, and practical subject as "Tracheotomy, with particular reference to the Causes of Death after the Operation, and the Rules for rendering the Operation more generally successful". Only one of the two essays received can be read, inasmuch as the author of the other failed to comply with the regulations by sending it in before Christmas-day—not, in fact, delivering it until midnight on that day. The subject for the Collegial Triennial Prize is, "The Radicles of the Lymphatic System in relation to the External and Internal Surfaces of the Body", the essays for which are to be sent in before Christmas-day 1876. The prize consists of the John Hunter Medal, executed in Gold to the value of fifty guineas, or, at the option of the successful author of the dissertation, of the said medal executed in bronze, with an *honorarium* of £50. The

subject for the Jacksonian Prize for the ensuing year is, "The Use of the Galvano-caustic in the Removal of Morbid Growths", the essays for which must be delivered before Christmas-day 1875.

HARVEIAN SOCIETY OF LONDON.

THE President and Council have issued cards of invitation to a *conversazione* to be held in the Society's rooms, Titchborne Street, Edgware Road, on Thursday evening next. The following is a list of the names of gentlemen proposed by the Council as officers of the Society for the year 1875. *President*: W. H. Broadbent, M.D. *Vice-Presidents*: J. Hall Davis, M.D.; O. A. Field, Esq.; W. Tilbury Fox, M.D.; T. Carr Jackson, Esq. *Treasurer*: Henry Power, Esq. *Honorary Secretaries*: Robert Farquharson, M.D.; H. E. Sewill, Esq. *Council*: James R. Lane, Esq.; E. Parker Young, Esq.; Septimus Gibbon, M.B.; A. J. Balmanno Squire, M.B.; G. De G. Griffith, Esq.; J. Lennox Browne, Esq.; W. F. Teevan, Esq.; W. H. Day, M.D.; John Easton, M.D.; E. Symes Thompson, M.D.; G. G. Gascoyen, Esq.; E. Cripps Lawrence, Esq. *Trustee* (in the place of the late Dr. T. Ballard): James E. Pollock, M.D.

THE BRITISH MUSEUM.

AFTER much inquiry, we are led to the conclusion that the death of the late Mr. Warren was directly connected with the unhealthy atmosphere in which he was forced to sit—in spite of his remonstrances, backed by the authority of his medical attendant; and, as we believe, also, that it is not unlikely that a similar fate may befall others who are unnecessarily submitted to the same unwholesome conditions, we feel it desirable to state some facts and conclusions. We are the more inclined to do so, because we doubt whether the trustees, with the best intentions, were in the right way to get at the real facts. Mr. E. A. Warren was head of the transcribing department. He had under him about ten transcribers or junior assistants, men engaged in copying titles written by senior assistants; also about a dozen attendants, and a staff of binders. All the titles written by the two dozen senior assistants and copied by the ten junior assistants passed through his hands. His work required great patience, memory, linguistic attainments, etc. He had been more than twenty years in the British Museum. During the greater part of the time, he was the head of the department. For some years, he had to sit in the lowest gallery around the reading-room. In all the galleries, the air is hot and heavy, and close and dry. But Mr. Warren and his staff sat on the actual ground-floor, in a windowless kind of tank, lighted by skylights. There, in winter, in the afternoons, the air becomes actually fetid, being tainted by the breaths of the twenty or thirty people employed. Even in the gallery on the ordinary first floor of the British Museum, the air is very trying. People who sit in it all day and every day feel it severely. They often gasp for breath; their temples throb; their skin on the forehead feels tense; nausea is often felt; the hands and feet are cold. A medical man who came to see a patient, asked to be taken out quickly. (He was not quite well that day.) If windows be opened to relieve these symptoms, cold draughts produce colds, rheumatisms, etc. Museum men become morbidly sensitive to cold, and they catch colds also from wet, etc., there being no room in which they can dry their clothes if wet, though many have to come long distances. The intermediate authorities, we are informed, repress complaints, saying they feel no bad effects themselves. But the heads of the printed book department have for more than twenty years had their private room and open fire, and are therefore exempted from the sufferings of their subordinates. The amount of sickness among the junior assistants is alarming. Several have died; several are suffering in health, and are justly alarmed as to the ultimate effects. Mr. Warren complained repeatedly, on their and his behalf. He received neither sympathy nor redress; at last, his medical man visited his room, and condemned it. Mr. Warren renewed his complaint, and quoted his authority. We are informed that the answer he received was: "How dare you bring a medical man into the Museum without leave of the trustees?" Nor did he ever get redress. After a

long time, consent was given to a window being cut in the wall of the room in which Mr. Warren sat. This got rid of the foul air a little, but it let in killing draughts of cold air. Mr. Warren went on complaining for a time, then despaired, and slowly sank. His strength, originally good, became lowered. He caught cold after cold, got a cough, and was at length laid up. Pleurisy, pneumonia, bronchitis, came in turns. He had not strength to shake them off. And so he died at the early age of thirty-eight, looking more like forty-eight, leaving a widow and two children. He constantly predicted that the Museum air would kill him, and wanted his colleagues to cry out and get something done. So also Mr. Deutsch used to predict his own death, and say, "When I die, there will be something done." Several of the junior assistants are in the hands of medical men, and are likely to follow Mr. Warren to the grave if not protected. The authorities seem disposed to stick up a screen here, a ventilator there. But there is no reason why the men should sit in such a hole. They sat upstairs for some time, till the authorities sent them down. Some time ago, before the cold set in, the trustees visited the room. They came about 1.30, when it was empty, when the window had been wide open for half-an-hour, and when the paper-indicators to mark draughts had been removed. They asked no questions of the victims, but found all sweet and good. It is not only the junior assistants who complain; the senior assistants also suffer greatly from colds, headaches, etc. The trustees, we fear, are insufficiently acquainted with their sufferings and complaints. The senior officers sit in their private rooms, beside their fires, and go home at mid-day to their dinners; while their subordinates are shivering in the long galleries, and unable to get even a cup of tea. It should be understood that this refers to the position of the assistants in the printed book department only: from the other departments we hear no such complaints.

CLINICAL SOCIETY OF LONDON.

THE following is the list of officers and council. The gentlemen whose names are marked with an asterisk (*) did not hold the same office during the preceding year. *President:* Sir William Jenner, Bart., M.D., K.C.B., D.C.L., F.R.S. *Vice-Presidents:* George Johnson, M.D., F.R.S.; *Henry Thompson, M.D.; Hermann Weber, M.D.; George W. Callender, F.R.S.; Timothy Holmes; *Jonathan Hutchinson. *Treasurer:* E. Headlam Greenhow, M.D., F.R.S. *Council:* Thomas Buzzard, M.D.; William Cayley, M.D.; Wm. Selby Church, M.D.; William Howship Dickinson, M.D.; *Dyce Duckworth, M.D.; *Charles Hilton Fagge, M.D.; *John Harley, M.D.; *J. Braxton Hicks, M.D., F.R.S.; Walter Moxon, M.D.; R. Douglas Powell, M.D.; Henry Arnott; *Edgar Barker; Richard Barwell; R. Brudenell Carter; John C. Langmore, M.B.; George Lawson; Arthur Treherne Norton; *James Rouse; *J. Soelberg Wells; Alfred Willett. *Honorary Secretaries:* Reginald Southey, M.D.; Thomas Pickering Pick.

UNQUALIFIED AND INCOMPETENT MIDWIFERY.

ON Monday, Mr. Richards, the deputy coroner for East Middlesex, held an inquiry at the Bricklayers' Arms, Bethnal Green, concerning the death of Mary Ann Prosser, aged 34, which arose during her confinement through being deprived of skilled treatment. The deceased was the wife of a labourer, residing at 2, Cumberland Place, Bethnal Green. On the 9th instant, she was taken in labour, and her husband called in Mrs. Corduroy and another female, named McCarthy, to attend her. The woman Corduroy, who gains a livelihood as nurse and midwife, delivered the deceased of a still-born premature child, and, after informing the husband that the deceased, who was covered merely by an old shawl and a bed-sheet, required stimulants and other attention, left. At half-past two o'clock the same day, the deceased having had attention of no kind for about three hours, Mr. Mainwaring was called, and found her dead; the husband having, in the meantime, been in search of medical aid from the parish authorities. Susan Corduroy stated that she had attended the deceased previously, and had successfully delivered her. She (Corduroy) was not a midwife of the

Maternity Charity, but received from the persons whom she attended whatever sum they could afford. The result of a *post mortem* examination by Mr. Mainwaring, showed that the brain and membranes were normal; the lungs congested, and the heart large and flabby and feeble; the liver was fatty, and the kidneys fatty and congested; the other viscera were healthy. The uterus was relaxed, and contained but little blood. The cause of death was syncope. The medical testimony fully proved that, had the deceased been seen by a medical man, and had stimulants administered to her, her life would in all likelihood have been spared. The woman Corduroy was cautioned against practising in future without the necessary qualification, and the inquiry closed with a verdict in accordance with the evidence.

THE LATE DR. CHARLTON.

A PUBLIC meeting has been held at the Wood Memorial Hall, Newcastle-on-Tyne, Mr. A. Potter, the Mayor, in the chair; at which it was resolved, "That, with a view to perpetuating the memory and the remembrance of the late Edward Charlton, M.D., D.C.L., it is desirable to found a scholarship in medicine at the University of Durham College of Medicine, Newcastle-on-Tyne, of which body he was president and joint lecturer on medicine, and also to place a bust in marble, or a portrait in oil, in the library of the Newcastle-on-Tyne Infirmary, of which institution he was senior physician, and chairman of the medical board". A committee, a treasurer, and two honorary secretaries, were then appointed, and a subscription list opened.

MEDICO-PSYCHOLOGICAL ASSOCIATION: THE W. AND S. TUKE PRIZE ESSAY.

SOME of the descendants of William and Samuel Tuke (the former of whom proposed the establishment of the York Retreat in 1792, and the latter wrote the "Description" of the humane system of treatment commenced there) having placed at the disposal of the Medico-Psychological Association the sum of one hundred guineas, the association offer a prize of this amount for "The best series of original cases and commentary, illustrative of the Somatic Etiology of various Forms of Insanity, accompanied, when possible, in fatal cases, by reports of *post mortem* examinations and microscopical preparations—their bearing on the symptoms being pointed out." Cases not seen by the writer may be cited, but must be distinguished from those actually witnessed by himself. The W. and S. Tuke Prize is open to all without restriction as to country, profession, etc., but the right is reserved to withhold it, should there be no essay of sufficient merit. Essays to be written in English, and not in the author's handwriting, must be sent with a sealed envelope, bearing the motto of the essay, and containing the name of the writer, to the honorary secretary, W. Rhys Williams, M.D., Bethlem Royal Hospital, not later than June 30th, 1876. The microscopical preparations, but not the essay, are to belong to the association.

DEATHS IN LONDON FROM THE COLD WEATHER.

THE Registrar-General states, that it was well established by the researches of Villermé and Edwards that young children die in considerable proportions by exposure to cold, and it was known in a general way that the winter is more fatal to old people than to young. The weekly tables carry us much further, and show that the mortality after twenty increases with age rapidly, and that after a determined law. Thus if we divide life into vicennial stages, then beginning at twenty, forty, sixty, eighty, the result in London in the six weeks of very cold weather, ending February 24th, 1855, was found to be that the mortality due to cold, at the four ages, was 2.0, 7.5, 44.9, 181.8; so rapidly did the power of resistance decline with age. Taking the increase of mortality by cold between twenty and forty as one, then the mortality became two, four, eight, and so on "doubling every nine years." The effects of the cold of the five weeks that ended on December 19th, have been tested in the same way, by comparing the deaths at each age with the deaths in the five previous average weeks. The deaths were raised from 6,967 to 9,871; so the excess due to

cold was 2,904 in the five weeks, and on an average 581 weekly. The mortality, higher than before, increased with age at the same rate; it was in every 1,000 living at the four ages, 2.2 at twenty to forty; 9.4 at forty to sixty; 46.9 at sixty to eighty; and 218.3 at eighty and upwards. The mortality from cold increased 8 per cent. for every year of age; or it doubled every nine years from the age of twenty, as it did in 1855. There is thus a law of mortality from excess of cold. But it must not, therefore, be assumed that the mortality is beyond control. The air we inhale at 28 deg. or lower, is raised not to blood-heat but to something approaching 98 deg. when it is exhaled; and as about a gallon of air is thus heated every minute, and as the evaporated vapour in the breath also carries off a considerable quantity of heat, the loss by the lungs is large, however warm the clothing may be. The cold is most effectively combated by exercise which excites the heating energy of the system; and warmth is sustained by nutritious food; by artificial heat; by warm woollen or fur clothing; and by the respirator, which retains the heat exhaled by respiration. The aged poor in this cold season of pressure require all these helps, and have claims not only upon their kindred, but upon their wealthier brethren.

PATHOLOGICAL SOCIETY OF LONDON.

THE following is the list of officers and council proposed for election for the year 1875. The gentlemen whose names are marked with an asterisk (*) were not on the council, or did not hold the same office during the preceding year. *President*: *George D. Pollock. *Vice-Presidents*: Lionel S. Beale, M.B., F.R.S.; *Wilson Fox, M.D., F.R.S.; Charles J. Hare, M.D.; *Sir William Jenner, Bart., M.D., K.C.B., D.C.L., F.R.S.; *Campbell De Morgan, F.R.S.; Carsten Hothouse; John W. Hulke, F.R.S.; Henry Lee. *Treasurer*: Charles Murchison, M.D., F.R.S. *Honorary Secretaries*: *Henry Green, M.D.; *William W. Wagstaffe. *Council*: *William Cayley, M.D.; Henry H. Crucknell, M.B.; Arthur Leared, M.D.; John W. Legg, M.D.; Joseph F. Payne, B.A., M.B.; Arthur J. Pollock, M.D.; R. Douglas Powell, M.D.; Philip H. Pye-Smith, M.D.; *Henry G. Sutton, M.B.; *C. Theodore Williams, M.D.; *Henry Arnott; W. Marrant Baker; *Marcus Beck; W. Fairlie Clarke, M.A.; M. Berkeley Hill, M.B.; *T. Carr Jackson; *Henry W. Kiallmark; Henry J. H. Lawrence; Francis Mason; *W. Spencer Watson.

HOSPITAL CONSTRUCTION.

AMONG the subjects brought forward for discussion before the American Public Health Association, at its recent meeting in Philadelphia, says the *Boston Medical Journal*, that of hospital construction occupied a prominent place. Several papers were read, testifying to the increasing interest which this matter has awakened in the minds of physicians and sanitarians. These contributions show that the drift of medical opinion is strongly towards single-storey pavilions and small wards. Fortified by statistics of the mortality in large metropolitan hospitals, as compared with that in field-hospitals, barracks, and private practice, the advocates of the reform in hospital construction have a strong position against those who would perpetuate the system of building piles of masonry, which sacrifice sanitary qualities to architectural display. It is noteworthy that of the five papers read at Philadelphia on this subject, only one was in any degree conservative on the question. Dr. William Pepper declared that the arguments which had been adduced had failed to convince him of the propriety of tearing down many of the large "palatial" hospitals, or of avoiding the building of similar structures in future, but had only shown him the necessity of remedying certain defects of construction, and of repressing certain abuses of administration, such as overcrowding wards, and keeping them constantly occupied. He conceded the utility, however, of having tents or temporary pavilions as outlying wards of large hospitals, in which to treat such cases as those of erysipelas, gangrene, and the contagious fevers. Assistant-Surgeon J. S. Billings, U.S.A., presented a very interesting paper, in which he took a decided position in favour of single-storey pavilions, built of inexpensive materials. The essay

contained many practical points and suggestions, the fruit of careful study and an extended experience. It is gratifying to record that the indications of a reform in hospital construction do not consist of well-conceived theories merely; but that hospital governments are disposed to apply the practical test of utility. The Massachusetts General Hospital has had two isolated single-storey pavilions under trial for some time, and the results are satisfactory. The extensive Presbyterian Hospital of Philadelphia will carry out the scheme with admirably planned details. The City Hospital of Boston, in the contemplated additions to its system of pavilions, will also adopt the advanced principles of construction upon the unanimous endorsement of the staff of the hospital. Other institutions will doubtless follow the example of those bold enough to accept the innovations urged by sanitarians, and we may confidently expect an improvement in the death-rates after surgical operations in hospitals.

RECENT URBAN MORTALITY.

DURING last week 4434 births and 4455 deaths were registered in London and twenty other large towns of the United Kingdom. The annual death-rate was 31 per 1000 in Edinburgh, 50 in Glasgow, and 27 in Dublin. The highest rates of mortality in the eighteen English towns were as follows:—In Birmingham 31 per 1000, Hull 31, Leeds 33, Norwich 34, Newcastle-on-Tyne 35, Liverpool 36, Nottingham 37, Oldham 39, Salford 40, Bradford 41, and Manchester 41. Scarlet fever continues fatally prevalent in Bradford, Hull, and Sheffield, and measles caused 20 deaths in Manchester and Salford. In London 1840 births and 1646 deaths were registered. The births were 509 and the deaths 113 below the average. The annual death-rate, which in the three previous weeks had been equal to 33, 32, and 30 per 1000, further declined last week to 25. To the seven principal zymotic diseases 165 deaths were referred, being 131 below the corrected average number of the week. Scarlet fever caused 65 of these deaths. The deaths referred to diseases of the respiratory organs were 685. The mean temperature of the air at Greenwich was 29.9 or 8.3 below the average. The mean was considerably below the average on each day of the week, and was lowest on Wednesday, when it was only 23.5, and the deficiency so great as 14.6.

SCOTLAND.

LECTURESHIP ON AURAL SURGERY IN GLASGOW UNIVERSITY.

AN arrangement has been come to in connection with this subject, similar to that indicated as the proper course in this JOURNAL a week or two ago. A committee has been formed, containing some very influential names, for the purpose of founding a lectureship on aural surgery. It is proposed that the lectureship should be in connection with the University and Western Infirmary. The committee propose to raise a sufficient sum of money to endow a lectureship, and to transfer the Dispensary to the Western Infirmary. An arrangement of this kind can hardly fail to meet the wishes of all concerned, and the proposed institution will be an important addition to the medical school.

GLASGOW MATERNITY HOSPITAL.

THE report read at the annual meeting of the contributors and subscribers to the Glasgow Maternity or Lying-in Hospital, shows that during the year 1,291 women have availed themselves of the benefits of the institution, being an increase of twenty-six, as compared with the number of last year. The increase was entirely in the number of outdoor cases, there being, as compared with last year, a decrease of seven in the internal department. This decrease was accounted for by the fact that certain parochial boards who annually sent a number of patients, no longer did so, as they had confinement-wards fitted up in their own hospitals. Three cases of death occurred in the hospital during the year. In each of these cases, the antecedent condition of the patient rendered a successful issue almost hopeless. The first case was one of puerperal convulsions, and the patient had been in a

state of complete insensibility for several hours before her admission. She was safely delivered of a stillborn child, and although, after two days, consciousness returned, and she appeared to be doing well, she finally, on the eighth day, sank from nervous exhaustion. In another, the woman had been weakly and suffering from chest-disease before her confinement; while the third case was one of pelvic deformity, with severe labour, and, although she was safely delivered, death resulted from puerperal fever. The percentage of fatal cases in the house was somewhat under 1 per cent. of the whole number treated; while in Glasgow, during the twelve months ending October 31st, 1874, a period almost continuous with that over which the report extends, and, at all events, quite comparable with it, there were 19,814 births and 113 deaths of mothers registered as from "metria and child-birth", giving a percentage of fatal cases of fifty-seven for the whole city. The percentage of deaths in the reported out-door cases was nearly the same as that of those delivered in the house. During the year there was no occurrence of septic or epidemic disease in the hospital, a result, doubtless to a great extent, due to the systematic and complete ventilation of the entire building, and the pains taken to secure the thorough cleanliness of the patients and their surroundings. The prevalence of epidemic disease in the city during the latter part of the year rendered the immunity enjoyed by the hospital a very gratifying circumstance. As a school for instruction in practical obstetrics, the institution had, during the past year, been more largely taken advantage of by students of medicine, and women in training for midwives and monthly nurses, than in any former year. "It remains to be seen whether the opening of the Western Infirmary, and the consequent comparative isolation of the University medical students to the western districts of the city, will have any effect in diminishing the attendance at our hospital. There need, we think, be no fear for the future, if the hospital continue to be conducted as hitherto, as its advantages as a field for clinical study are so great, and in Glasgow so unique, that it will always attract a fair share of students desirous of acquiring practical instruction in midwifery, which is one of the most important branches of our profession."

IRELAND.

SCARLATINA still continues its ravages in Belfast, thirty deaths being registered last week; and during the past five weeks the mortality from this affection has amounted to 141.

DR. QUINAN, who acted for many years as Honorary Secretary to the Irish Medical Association, has resigned; and the Council of that body, in accepting his retirement, record the strong feelings which it entertains of the value of the arduous and self-denying services which he has rendered to the Association during the past twenty-three years.

ROYAL COLLEGE OF SURGEONS.

MR. JOHN HAMILTON, surgeon to the Richmond, Hardwicke, and Whitworth Hospitals, etc., has signified his intention to come forward as a candidate for the vice-presidency of this college. The election, which is in the hands of the fellows, will not take place until June next: but several months' notice is usually given by those wishing to contest the post. At present, no other candidate has offered to oppose Mr. Hamilton.

COLLEGE OF PHYSICIANS: NEW CHARTER.

A MEMORIAL from five Fellows of this Institution has been presented to the Lord-Lieutenant in reference to the proposed new charter, by which it is intended that the power of election by ballot of Fellows and Officers shall be obtained, and that a new grade between Licentiates and Fellows, styled members, shall be instituted. The memorialists, who are men of position and influence (Sir Dominic Corrigan, M.D.; Edward B. Sinclair, M.D.; Robert D. Lyons, M.B.; Francis R. Cruise, M.D.; Samuel Haughton, M.D., F.R.S.), object strongly to these changes; and show, in reference to the first point, that from its

foundation, in 1692, to 1828, upwards of one hundred and thirty years, there was open voting; but in 1828 the College assumed the power of voting by ballot; and they state that, since that period, candidates have been rejected who should not have been black-beaned or excluded by secret voting. The College consists at present of fifty-five Fellows; but, of these, some are resident abroad, others have left the profession for other pursuits, and some cease to attend the College meetings; and, during the year 1873, the average attendance, except on one occasion, was only fifteen; and the memorialists say that, with so small a body of Fellows and such small attendances, the power of election by ballot could be controlled by a very small number, and could be diverted to any purpose. They also assert that there is a monopoly of offices in the possession of a small handful of the Fellows, which at present diminishes greatly the influence and prestige which a body constituted like the College of Physicians was intended to exercise. That there is a select majority of the electors who share year after year in the emoluments of the institution there can be no denial, as the records of the College will show, the same names filling one office or another repeatedly.

STEEVENS' HOSPITAL.

ON Saturday last, the students of Steevens' Hospital presented Dr. Boskey, senior demonstrator of anatomy and formerly house-surgeon of the hospital, with a handsome clock and illuminated address, as a token of their esteem for him as a friend and teacher. Dr. Boskey has been attached to the institution ever since he became a qualified practitioner, and was previously one of the most distinguished pupils of the hospital and school. He is held in high esteem not only by the pupils, but also by his colleagues and the profession generally.

THE LATE DR. SHIELL.

THE following resolution was recently passed at a meeting of the Governors of the District Lunatic Asylum at Enniscorthy:—"That we cannot separate without recording our sincere respect at the lamented death of Thomas Wildridge Shiell, M.B., who was the talented, kind, and courteous resident medical superintendent of this institution from its opening in January 1868, to 19th October 1874, during which period his continuous attention was devoted to the welfare of the patients, and to the interests of this institution generally, which frequently called forth the marked approval of the inspectors and this Board; and we take this opportunity of expressing our deep sympathy with Mrs. Shiell in her bereavement."

THE WATER-SUPPLY OF DOWNPATRICK.

SEVERAL months since, a letter was received by the Town Commissioners of Downpatrick from the medical practitioners resident there, stating that in their opinion the water-supply of the town was impure, and that it had caused a considerable amount of disease. The Commissioners sent samples of the suspected water to Dr. Hodges of Belfast, who analysed them, and reported that, with the exception of two, they were all impure, and no better than "diluted sewage". The guardians, being the sanitary authorities, lately consulted their engineer as to the cost of obtaining a pure supply of water, who found that £700 would be sufficient to execute the necessary works. The subject is one of considerable importance, and the money required to be expended should not deter the sanitary authorities of the town from having, despite all opposition, a plentiful supply of pure water for the inhabitants.

THE DUBLIN PUBLIC HEALTH COMMITTEE AND THE MEDICAL OFFICERS.

THE above obstructive body, having been ordered by the Local Government Board to pay the medical officers the very munificent salaries of £25 *per annum*, is about to take counsel's opinion as to the possibility of refusing to obey the mandate of the Board. In other words, the Committee are adopting any method, legal and otherwise, to obstruct and evade the Act of Parliament. We do not see that the medical officers have much for which to thank the Local Government Board, as we must, in the words of the order of the Board to the Committee, characterise the salaries fixed by the Board in the same language as the Board characterised those fixed by the Committee, that is, "*totally inadequate*".

NAVAL MEDICAL SERVICE.

THE *Scotsman* is informed that the statement of grievances placed before the First Lord of the Admiralty recently by Mr. Ernest Hart, on behalf of a deputation of the British Medical Association, has induced Mr. Ward Hunt to propose to the Treasury certain improvements in pay and position. If the Admiralty scheme should be approved, there will be a promotion of several senior staff-surgeons to the rank of deputy-inspectors-general of hospitals and fleets. It is stated also that the title of "Second-Class Staff-Surgeon", which was complained of as being absurd, will be abolished.

We are enabled to state that the whole of the documents laid before the First Lord by the deputation of the British Medical Association have lately been under his consideration, but we are not yet acquainted with his decision. A new competition is announced for vacancies; it is, however, by no means desirable that candidates should present themselves in the present state of uncertainty and discontent in the department.

THE RECENT VIVISECTION TRIAL AT NORWICH.

It is announced by telegraph in the daily papers that, at the annual meeting of the Académie des Sciences of Paris, Dr. Magnan, who was recently one of the defendants in the recent prosecution at Norwich, was awarded a prize of £100 sterling for those very experiments as to the effect of alcohol on quadrupeds.

Most of the French medical journals contain comments on the above persecution. *La Tribune Médicale* says: "We do not lay stress on the feelings which influenced the magistrates, nor do we make any comments, believing that the open and distinct declarations of such men as Dr. Copeman and Sir James Paget will effectually dispose of the singular assertions of Mr. Tufnell, the sensitive sportsman, and Sir W. Fergusson, the best of physiologists."

The *Progrès Médical* says:—"If there be any country in the world in which medical men offer a liberal and generous hospitality to their colleagues, that country is certainly England. To this rule, however, there was a painful exception at the late meeting of the British Medical Association at Norwich, in the case of one of the most distinguished and worthy of the French visitors. If these confirmatory experiments were not allowed, how would it be possible to distinguish truth from error? These experiments are surely justifiable when a scientific visitor, who has made discoveries which are valuable to humanity at large, wishes to demonstrate their reality to an important meeting of medical men. These experiments were so much the more justifiable in the case under consideration, because M. Magnan's experiments had never previously been made in England, and also because this physiologist operated with the greatest dexterity."

L'Union Médicale has a long and indignant article, which we do not quote, because it is so long, and also because it travels into matter which is wide of the mark. We hear from an occasional correspondent that the course taken by Sir W. Fergusson and Mr. Tufnell has caused "general indignation, and the utmost surprise that so much ignorance of the objects and means of scientific research should be exhibited by gentlemen who might be expected to know better, and especially by one who is a member of the English Institute" (the Royal Society).

SIR,—May I beg the favour that you will publish in your next number the enclosed letter, which was despatched before your last number came out.

Yours faithfully, WM. FERGUSSON.

16, George Street, Hanover Square, W., 28th Dec., 1874.

"16, George Street, Hanover Square, W., 24th December, 1874.

"My dear Dr. Copeman,—I have to acknowledge your communication of the 21st instant, enclosing copy of resolution passed by the local Executive Committee, for Norwich, of the British Medical Association. When in Norwich on the 9th instant, I was not aware that any professional man in the country was seriously involved in the question raised by the Society for the Suppression of Cruelty to Animals. I only learnt this from the public papers afterwards.

"My opinions were given without reference to individuals. I regret to find that those opinions are not in accordance with those of the Executive Committee. The gentlemen on that Committee having voluntarily given theirs, my views were squeezed from me by force of

law. Surely I am as much entitled to independent thought as those gentlemen are!

"I feel bound to add that I disagree with the first part of the resolution, and that I have a firm conviction that the recent action of the Society for the Suppression of Cruelty to Animals will be productive of much good in every rational sense.

"Reciprocating the good wishes of the season,

"I remain, yours very sincerely, WM. FERGUSSON.

"Dr. Copeman, Norwich."

SIR,—In all such cases, it is a thousand pities that medical men do not act as their own advocates, instead of employing lawyers who cannot enter into their ideas and objects.

The question in this case was a most simple one. Is it justifiable to torture and kill animals in order to support human life? and was this particular experiment conducive to this end. If the worthy justices of Norwich had decided the first point in the negative, we must resort to vegetable diet, and medical knowledge must be acquired only by observation of human suffering. Certainly in many diseases our treatment is no better than that of Hippocrates; but to gain his knowledge he allowed numbers of human beings to perish unaided, and simply recorded their symptoms and sufferings as a guide to his system of treatment.

The greatest advances in medical knowledge have unquestionably been derived from experiments on animals. It is now fifty years or more since Magendie starved his half dozen dogs on rich soup, while the other dogs lived well on the refuse of the meat. That experiment revolutionised the dietetic treatment of patients with chronic complaints, and saved more thousands of human lives than it sacrificed single dogs.

As to the cruelty and uselessness of the experiment, the only wonder is that the justices did not stop the case when they found that the only suffering endured by the animals was being tied down and having a vein opened. Transfusion of blood is not an unheard-of operation; and if it be allowable to perform this experiment on man in the hope of saving a single life, how utterly absurd is it to object to a similar operation on a few animals which may probably result in the saving the lives of multitudes of human beings.

The experiment of M. Magnan is of the greatest interest; and the investigation must be pursued. At present, nothing certain is known of the proximate cause of epilepsy, notwithstanding the investigations of Schroeder Van der Kolk. The only chance of our being able to cope with this disease is the induction of it in animals and their dissection immediately after death. If M. Magnan can to a certainty produce epilepsy in dogs, by any means whatever, he will have opened up a great avenue to knowledge.

The Society for Prevention of Cruelty to Animals may find plenty of occupation in our streets and thoroughfares, without interfering with the legitimate experiments of the most benevolent and self-denying profession in the world. The suffering caused by bearing-reins and double bits to horses in any one day in London, is greater than that from the experiments of all the physiologists in Europe in a century.

If opening a vein be so cruel to an animal, why does not this Society look after the butchers, and eaters of veal? Every calf prepared for food in London undergoes greater torture than the two (now celebrated) dogs underwent at Norwich; one of whom recovered after a severe fit of drunkenness, and the other died insensible, like thousands of human beings, in a fit of epilepsy.

Let us hope that the nature of epilepsy may be further investigated, and also the kindred disease of canine madness—if not in England, where we house our hounds better than our fellow creatures, yet in countries where the lives of human beings are more valued than the comforts and luxuries of their dogs.

I am, Sir, yours, etc.,

M.D. OF 1834.

SIR,—I never remember reading of such frivolous and vexatious legal proceedings being taken against five medical gentlemen, as those reported in the last JOURNAL. If the Society for the Prevention of Cruelty to Animals have no better way of showing their humanity than instituting proceedings to load medical gentlemen with obloquy for sanctioning the performance of two simple experiments on two dogs, the sooner they betake themselves to some more honourable employment the better. This is straining at a gnat, and swallowing a camel. Truly, we live in a day when sentimental sensational nonsense is very rife, or we should never hear of such frivolous and vexatious proceedings as these; but that gentlemen of eminence and standing in the medical profession should come forward and give such evidence as they did, is perfectly astounding. It is impossible to estimate the injury that such proceedings must have upon science and humanity, especially when

men of such eminence are ready to come forward and swear that such experiments are unnecessary and cruel, in the face of many who witnessed them, who are a sufficient guarantee to the contrary. That laymen, whose sensibilities are easily shocked, should not be allowed to be present at operations, whether surgical or experimental, is quite evident; * as, but for this unfortunate element in the matter, it is most probable we should have heard nothing of these vexatious proceedings; but that by no means exculpates the medical element for their most unprofessional conduct.

It is quite certain that all the gentlemen implicated in these frivolous and vexatious proceedings ought to be greatly ashamed of themselves; and, as a simple act of justice, they ought to tender an apology to the five gentlemen whose characters they have done their best to injure in a very tender part.

Dec. 24th, 1874.

I am, Sir, your obedient Servant,
A LIVERPOOL ASSOCIATE.

THE ABUSE OF HOSPITALS.

WE are requested to publish the following memorial, which is in course of signature:

To the President and Committee of Council of the British Medical Association.

We, the undersigned, members of the British Medical Association and others, beg most respectfully to request the Committee of Council to take into its consideration the relation of the medical profession to the hospitals and free dispensaries throughout the kingdom.

Your memorialists are convinced that the manner in which these institutions (with some few exceptions) are at present conducted, inflicts a serious injury upon many most deserving members of our profession, while the indiscriminate (or almost indiscriminate) bestowal of gratuitous medical relief upon all applicants lowers the whole scale of our professional remuneration, is far from being a real boon to the working classes themselves, and cannot fail, in the long run, to have a prejudicial influence upon the nation at large.

The question to which we venture to draw the attention of the Committee of Council has been much discussed of late years both in the medical press and in the lay periodicals. It is not necessary, therefore, that we should enter into any details respecting it. We may, however, mention that there are three facts which have a very important bearing upon it, and which make the present time particularly opportune for entertaining it. These are (1) the improvement which is now rapidly taking place in the social and political condition of the industrial classes; (2) the amendments which have lately been made in the administration of parochial medical relief; and (3) the increase within the last few years in the length and expense of medical education. These facts are admitted by all, and their concurrence has led, we believe, to a very general opinion among those who are conversant with the working of the free dispensaries and hospitals that some changes are necessary in order to bring these institutions into harmony with the altered conditions of the present day.

As it is desirable that any changes which may be necessary should be duly weighed by a body which fairly represents the medical profession, and should be recommended by high authority, so as to carry along with them the assent of the lay governors of the "Medical Charities", your memorialists pray you to take this important subject into your consideration.

This memorial has been already signed by—Sir William Jenner, Sir William Gull, Sir William Fergusson, Sir Rutherford Alcock, Mr. Prescott Hewett, Mr. Erichsen, Dr. George Johnson, Dr. Hawksley, Dr. J. W. Ogle, Dr. A. P. Stewart, Mr. John Wood, Dr. Arlidge (Stoke-upon-Trent), Dr. John Harley, Dr. A. Meadows, Dr. Joseph Rogers, Dr. Cayley, Dr. Wiltshire, Dr. Robert J. Lee, Mr. Richard Davy, Mr. Fairlie Clarke, Mr. Nelson Hardy, Dr. Ford Anderson, Dr. Cooper Rose, Mr. J. B. Curgiven, Dr. Morton (Kilburn), Mr. R. H. S. Carpenter, Dr. Grigg, Dr. Cruicknell, Dr. Heywood Smith, Mr. Bellamy, Mr. Spencer Watson, Mr. Parker Young, Dr. Dewar, Mr. S. Alford, Mr. C. J. Lord, Dr. Herbert Evans, Mr. F. H. Gervis, Dr. Purcell, Mr. Llewellyn Thomas, Mr. F. A. Hill, Mr. Platt, Mr. Otley Lovell, Dr. King, Mr. F. Lewis, Dr. Floyce, Dr. James Murray, Dr. Langstone, Mr. Whitney, Dr. Moore, Dr. Leslie, Mr. E. G. Pottle, Mr. G. L. Priddle, Mr. C. W. Pearce, Mr. J. Lynch, Mr. R. Debenham, Dr. J. Godfrey, Mr. H. Beattie, Mr. T. Richardson, Mr. A. Harris, Mr. J. A. Cummin, Mr. F. G. Aubin, Dr. Macfee,

* We believe that the only layman present was introduced, without authority, by Mr. Tufnell.

Mr. H. Kay, Mr. F. Mahony, Mr. J. W. Kay, Mr. L. B. Brunton, Dr. R. S. Nightingale, Mr. H. Taynton, Mr. J. Arthur, Mr. W. J. Whitten, Mr. T. J. Hughes, Dr. L. Llewellyn, Mr. M. Coleman, Mr. J. R. Pottle, Mr. E. Sison, Mr. M. J. O'Connor, Mr. G. A. Rogers, Mr. H. Hanks, Mr. C. Nelham, Mr. J. Horton, Mr. T. C. Cowars, Mr. E. Snell, Mr. C. Hawker, Mr. R. H. Anderson, Mr. J. McAndrew, Mr. C. W. Vickers, Mr. George W. Sharp, Mr. W. H. Cringle, Mr. T. S. Gimson, Mr. R. Verley, Mr. B. A. Duncan, Mr. W. Smith.

Medical men who approve of the foregoing memorial, and wish their names to be added to it, are requested to communicate with Dr. Meadows, 27, George Street, Hanover Square, or with Mr. Fairlie Clarke, 12, Mansfield Street, Cavendish Square, W.

THE SHIPTON RAILWAY ACCIDENT.

WE are indebted to Mr. Symonds, Surgeon to the Radcliffe Infirmary, and to Mr. Morgan, House-Surgeon of the Infirmary, for the following particulars of the cases admitted into the Infirmary from the Shipton railway accident.

There were fifty-two admitted on the first night, most of whom were wretchedly cold and wet. One case only required operation, and that was a man whose right arm was crushed off just below the elbow. The heads of the radius and ulna were removed, and the condyles of the humerus sawn off. This man also had an extensive laceration of the scalp.

Five cases of compound fracture were admitted:—1. A woman, aged about 30, had compound fracture of the right radius and ulna; she also had extensive laceration of the cheek: progressing favourably; 2. A woman, aged 45, had compound fracture of the left tibia and fibula, and fracture of the right femur: doing well; 3. A man, aged 26, had compound fracture of the left radius and ulna, severe abrasion of the whole of the arm, and several contusions and cuts about the head; 4. A man, aged about 50, had compound fracture into the right ankle-joint: doing well; 5. A man, aged 22, had compound fracture of the left radius and ulna, and several wounds about the head: doing well. All these patients were much shaken and bruised. Four cerebral cases were admitted:—1. A girl, aged 20, had bleeding from the left ear, dilated pupils (both equally so), coma, and fracture of the radius and ulna. She was quite wet, and very cold and collapsed. She became conscious on the 28th, and left facial paralysis appeared. She passes motions and urine in bed; complains of pain in the head, and is in a critical condition. 2. A man, aged 28, remained unconscious for two days after admission. His pupils acted, but his breathing was stertorous. The third day, he could be aroused, but soon relapsed into his drowsy condition. To-day (Tuesday), he is much better. Ecchymosis of both eyelids exists. A man, aged 39, was in a condition similar to the previous case, but much bruised about the face, and his nose was broken. He answers questions to-day, but wanders at intervals. 4. A girl, aged 5, has been unconscious since admission. She was quite collapsed when brought to the infirmary. The body felt very cold, and there was vomiting at short intervals. At the present time, she has diaphragmatic breathing, some rigidity of limbs, and widely dilated pupils; no bleeding from the ears.

Several cases of extensive lacerations and bruising were admitted. The wounds, if large, were sewn up, and have for the most part healed exceedingly well. One poor woman is exceedingly bruised and crushed about the legs, but has no fracture.

A woman, aged about 50, has her right clavicle fractured and several ribs broken.

A man, aged about 50, has fracture of the pelvis (or innominatum) and of the right femur, the other leg being much bruised.

Two cases have died since admission: one (a man) from rupture of some internal organ; the other (a girl) from injuries to the chest. No post mortem examination has yet been made.

Five patients have been discharged, who suffered mainly from severe shaking and exposure to cold. Thirty-seven patients remain in the house. A noticeable fact is the great pain in the back that most of the patients complained of experiencing. Some had been lying out in the snow, and had become extremely cold; but a plentiful supply of warm blankets and hot beef-tea in time furnished the warmth they had need of. The cases not individually mentioned were for the most part bruised and shaken; but, after resting in bed since the accident, they are now doing well.

We are not able to furnish much detail, as the sudden influx of so large a number of patients has allowed but little time for note-taking.

THE HAMPSSTEAD HOSPITAL.

SIR,—I must send a reply to your article on "A More Imaginary Grievance can hardly be conceived", than that we Hampstead and St. Pancras people feel we are suffering from.

In the first place, it is not Hampstead alone, but the residents and vestries of Hampstead and St. Pancras, representing 260,000 of the inhabitants of London, about one-twelfth of the population, that are thus, you say, deluded; they include all the resident medical men, not altogether excepting Mr. Lord, who, although he does not agree in the open question of infection with us and many others in the profession, as Dr. Budd (Bristol), the late Dr. Hillier, medical officer of St. Pancras, etc., admits that we had little or no small-pox in Hampstead until after the hospital was opened. Your article on this doubtful open question is very severe on us. Had you lived in the neighbourhood in 1871, after the opening of the Small-pox hospital, you would have seen, and therefore believed. Mr. Lord's report for 1871-72 shows that thirty residents of Hampstead died from small-pox after the opening of the hospital. Of these, fifteen lived within at least one-third of a mile from the hospital. In Fleet Road, the continuation of the valley, at the head of which the hospital is situated, in sixty-one houses there were eighty-nine cases of small-pox: all these, I believe, occurring after the opening of the hospital. Amongst my patients, the infection in 1871 picked out nearly all who were not revaccinated. We had no cases of small-pox before the hospital was opened. Many cases can be traced to infection received from the hospital after it was opened, from nurses, conveyances, sewers down the line of the Fleet valley. Surely it is a recognised fact that infection can be conveyed by atmospheric dispersion in the form of impalpable dust, or by the poison being wafted through the air in the form of nebulae; or why do we hang sheets steeped in a disinfectant in front of the doors of infected rooms?

We know the subtle nature of the scent by which the dog discovers the game, also the aroma from musk; and can it be denied that infection may be conveyed through the atmosphere, and carried along by currents of air? The late Dr. Hillier traced infection carried by the wind from a case to a distance of two hundred feet. Dr. Budd (Bristol) traced small-pox spreading from flock to flock of sheep down a valley, carried, he supposes, by currents of air; whereas a flock nearer the infected sheep, when separated by rising ground, escaped. Professor Tyndall considers that dry particles float in the air, acting, to all intents and purposes, as a seed and source of disease. The smell from the knacker's establishment at Islington can be detected for miles to the windward. All this shows the more than probability that infection may spread far beyond the confines of the hospital.

The site of the hospital is on the south slope at the head of the Fleet Valley, on a clay soil, surrounded by rising ground; it is about three hundred yards from the commencement of the heath, and not, as you state, at least one mile south-east of it, and that part nearest to the hospital which is called the Lower Heath is much frequented during holidays, the chief donkey-riding going on there, consequently drawing large crowds of young people. The North London Railway and Station is within three hundred yards of the hospital. The public road to Hampstead Heath, and the only access to the hospital, is within one hundred yards of it.

A footpath from North London passes close under the hospital wall, and tens of thousands going to the Heath on holidays must pass close to the hospital, who, you say in your article, need not come within sixty-two feet of it.

The report of officers of health, it must be remembered, is as regards the numbers of deaths, whereas they know little or nothing as to the actual number of cases in and about a neighbourhood.

As regards Homerton and Stockwell Hospitals, they are both on gravel soil, and on a flat or elevated position; and it is well known that property has depreciated in their neighbourhoods. All the medical men in this neighbourhood can testify that it was no imaginary grievance that we suffered from in 1871 after the hospital was established.

Whether the alarm be well founded or not, it exists, and will bring ruin upon this hitherto healthy and beautiful locality, teeming as it does with charitable institutions and numerous schools.

I am, yours truly, STEPHEN S. ALFORD, F.R.C.S.

Haverstock Hill, December 28th, 1874.

* * * This letter is a striking instance of the loose sort of statements which have been and are being made on this question. Whether or not Dr. Budd of Bristol and the late Dr. Hillier agree with the Hamp-

stead people we are doubtful; but we know that the latter have not yet produced a single medical man of special experience in the question under discussion to support their view, nor have they established a single case of small-pox due to infection from the hospital. Mr. Alford says that many cases of infection can be traced to infection received from the hospital, from nurses, conveyances, and sewers. If this be true, then why not trace such cases? Let them, and the evidence in support of them, be produced and laid before competent authority for consideration. Mr. Alford further says:—"Surely it is a recognised fact that infection can be conveyed by atmospheric dispersion." This most surely is not a recognised fact, inasmuch as it is the condensation, not the dispersion, of infected air which gives rise to disease. If Mr. Alford, however, mean that some diseases are communicated through the air, we are not aware that we or anybody else denied that. We in fact admitted it, but contended that the distance such diseases could be communicated was a *limited* one; and we can hardly imagine that Mr. Alford would allege that it was *without limit*. We then proceeded to show what experience taught us as to the extent of the said distance, and we showed that experience taught us that the infective power of the infectious diseases with which we are acquainted was powerless at the distance of a few feet from the infected person or thing; and Mr. Alford has not made the faintest attempt to invalidate the evidence which we adduced on the subject. Dr. Budd of Bristol may have supposed that infection was conveyed in currents of air in the case of the sheep referred to; but Dr. Budd was too good a man to think that, because he *supposed* a thing took place, therefore it did take place, as Mr. Alford, in his letter, implies. Dr. Budd further well knew that science is neither founded upon isolated occurrences, nor on the *suppositions* of individuals, however exalted, but upon well ascertained facts collected from an extensive field of inquiry. Mr. Alford tells us that the hospital is only three hundred yards, *i.e.*, nine hundred feet, from the Heath, instead of a mile, as we said. The correctness or incorrectness of this depends upon the question, What does the Heath include? This is a matter which, in our opinion, does not require to be contested, inasmuch as a distance of three hundred yards is far more than experience warrants us in demanding for the purpose of separating the infectious sick from the healthy. The footpath referred to is the Fleet Road, and the distance from the centre of the lowermost pavilion of the present building to the boundary wall in the said road is sixty-two feet. At the north-east corner, for a few paces, this distance falls to forty feet—a fact which in no way affects the position taken in the article. In the new building, moreover, the distance at this boundary of the hospital may be increased. We may here say in passing, that the fact of the hospital being on a clay soil is true of nearly every London hospital, and that, if hospitals for London are to be built only on gravel, they cannot be built at all, at least in London. The statement that there was little or no small-pox until the opening of the Hampstead Hospital means, of course, that there was some; but the statement is open to the gravest doubt in face of the fact that small-pox was epidemic in St. Pancras and Kentish Town, at the very doors of the Hampstead parish, as the following statement of Dr. Stevenson, Medical Officer of Health for these districts, will prove:—"The district was thoroughly infected with the disease long before the hospital was opened for the reception of small-pox patients, and as the number of patients in the hospitals increased, small-pox decreased in Kentish Town, subsequently increasing as the number of patients in the hospital decreased. Right up to the confines of Hampstead parish, Kentish Town was steeped in small-pox, and the *throughfare leading from the hospital to this parish was affected before ever a small-pox patient was admitted into Hampstead Hospital.*" The italics are ours. Supposing, however, that it were established that not a single case of small-pox occurred until *after* the hospital had been opened; what would it prove in face of the fact that numbers of persons were passing between Hampstead and infected districts? that small-pox was general over England and the continent of Europe? and that districts without such a hospital as existed at Hampstead, suffered as much as, if not more than, Hampstead itself? Moreover, the epidemic of 1870-71, like all other epidemics, appeared in the most crowded districts of the metropolis, to wit, the East End of London, to which it was for some time confined. In the forty-fourth week of the year, the deaths, chiefly East End deaths, amounted to twenty-seven; and in the forty-fifth they rose to forty, "of which no less than twenty-two were in the East districts, including Shoreditch, Bethnal Green, and Whitechapel" (*Reg. Gen. Rep.*, 1871). Hampstead, as an open, well ventilated district, would be one of the last places affected. To argue simply that because small-pox appeared at Hampstead after the opening of the hospital, therefore the hospital was the cause of the small-pox, is about as absurd a piece of reasoning as has been put forward on this subject by the Hampstead complainants.

STATE MEDICINE QUALIFICATION.

UNIVERSITY OF LONDON.

THE Committee on Examinations in Medicine has, we understand, presented a report to the Senate on the subject of proposed certificates of Proficiency in Public Health, of which the following is an outline.

1. That a Special Examination be instituted in the subjects which relate to Public Health; and that a Certificate of Proficiency in these subjects be granted to Candidates who shall have passed this Examination.

2. That any Bachelor of Medicine of this University be admissible to this Examination, after an interval of a year from his passing the Second M.B. Examination.

3. That the subjects of Examination shall be as follows:—(a) *Chemistry and Microscopy*, in relation to the examination of Air, Water, and Food. (b) *Meteorology and Geology*, as far as they bear on the duties of Health Officers. (c) *Vital Statistics*, in reference to the methods employed for determining the Health of a Community. (d) *Hygiene*—general principles of Hygiene. (e) *Medicine*, in reference to the origin, spread, and method of prevention of Diseases generally, but especially those of the Epidemic class. (f) *Sanitary Engineering*, as far as regards the arrangements connected with Water-supply, Sewerage, and Ventilation. (g) *Sanitary Law*, as far as it relates to the duties of Officer of Health.

4. That the Examination shall extend over Four days, and shall be both written and practical.

6. That if in the opinion of the Examiners sufficient merit be evinced, the Candidate who shall distinguish himself the most shall receive a Gold Medal of the value of Five Pounds.

ASSOCIATION INTELLIGENCE.

COMMITTEE OF COUNCIL.

NOTICE OF MEETING.

A MEETING of the Committee of Council will be held at the Office of the Association, 36, Great Queen Street, London, on Thursday, the 14th day of January next, at 3 o'clock in the afternoon.

FRANCIS FOWKE,
General Secretary.

36, Great Queen Street, London, December 23rd, 1874.

BATH AND BRISTOL BRANCH.

THE third ordinary meeting of this Branch will be held at the Royal Hotel, College Green, Bristol, on Thursday, January 14th, at 7.30 P.M.; FREDERICK MASON, Esq., President, in the Chair.

E. C. BOARD, *Honorary Secretary*.

Clifton, December 29th, 1874.

SOUTH OF IRELAND BRANCH: ORDINARY MEETING.

THE second meeting of the session 1874-75 was held in the Theatre of the Royal Cork Institution, on December 9th; Dr. THOMAS GREGG, President, in the Chair. There was a large attendance of members and students.

The HONORARY SECRETARY read the minutes of the previous meeting, at which two interesting cases were brought forward; one of Spontaneous Cure of Ovarian Cyst, by Dr. W. J. Cummins; the other of Exophthalmic Goitre, by Dr. H. M. Jones.

New Members.—The following new members were elected: R. Barrett, M.D., Macroom; J. McDonough, L.R.C.C.P., Killarney; T. Sandiford, M.D., Castlemartyr; G. Hickson, L.R.C.C.P., Killarney; L. T. Griffin, L.R.C.C.P., Lond., Killarney; and Dr. Jennings, Queen's College, Cork.

Rules of Debate.—The SECRETARY read the rules of debate. No communication is to occupy a longer period than a quarter of an hour in reading; and any speaker is limited to ten minutes in discussion. Members from the country are to get priority in their communications, to enable them to return early, if required.

Excision of the Eye.—Dr. JONES exhibited an eye he had excised, in which there had been a bright red reflection from the pupil, the same as that noticed in glioma. The history of the case also was similar, but the age of the patient excluded the idea, as he was a man about forty. On examination with the ophthalmoscope, no tumour was discernible;

nothing save a dark red fundus. There was very little pain; the tension of the eye was greatly diminished. The patient presented himself after some months with a collapsed ball, which was painful, and the fellow eye was commencing to water. He now consented to enucleation. The lens was cretaceous; the iris adherent to the cornea; the choroid atrophied; the vitreous humour gone; a thick and tough membrane supported the lens posteriorly; and in the posterior chamber was some cheesy matter. The optic nerve was healthy. The man is doing well.

Case of Exophthalmos.—Dr. JONES exhibited a remarkable case of exophthalmos in a child, which followed a fall on the temple. The protrusion took place about twenty-four hours after the injury; and on the seventh day, when he saw the child, the eye was completely protruded from the orbit. There was still some slight depression and protrusion, but the vision was completely restored. The treatment consisted of a compress kept constantly on the ball, and the use of atropine.

Death from Haemorrhage during Typhoid Fever.—Dr. JONES exhibited the viscera and temperature chart of a woman, who had died of severe haemorrhage during the third week of typhoid fever, in the Cork Fever Hospital. This was an interesting case, inasmuch as the patient was admitted with all the characteristic symptoms and rash of typhus, and was heavily mottled; nor did the ochry stools appear until she was five days in hospital. There was a well marked enlargement of Peyer's patches with deposit, and the usual pathological appearances present in typhoid. The spleen was enlarged and soft, and a large hæmorrhagic infarction was present in its substance.

Cardiac Embolism occurring twice.—Dr. DAY contributed the notes of a case (he believed the only one on record) of cardiac embolism occurring twice in the same subject, at an interval of eighteen months. On both occasions, amputation was resorted to successfully for gangrene of the extremities. The young gentleman now rolls himself about in a little carriage, and is in perfect health.

Removal of Cranial Bones.—Dr. HAYES of Tralee exhibited the entire parietal and half the frontal bone of a woman, who had in a drunken state fallen into a turf fire in last May, and who is now alive and doing her business. The bones separated at the sutures in October, and came away, leaving a raw granular surface underneath. The bones were apparently forced out and loosened at the sutures by the formation of purulent matter underneath. The interior of the bones and the grooves for the meningeal arteries and frontal sinuses were almost obliterated. The frontal bone had separated completely at the original line of junction. Very lately the woman, for the first time since her immediate recovery from the accident, appeared to be threatened with head symptoms.

Arterio-Capillary Fibrosis.—Dr. ATKINS exhibited some drawings of arterio-capillary fibrosis, and also had several microscopical preparations of the same pathological condition; but time did not permit their examination. The description of them was, therefore, adjourned.

BATH AND BRISTOL BRANCH: ORDINARY MEETING.

THE second ordinary meeting of the session was held at the York House, Bath, on Thursday evening, December 3rd; F. MASON, Esq., President, in the chair. There were present forty members and three visitors.

New Members.—The following gentlemen were elected members of the Association and of the Branch:—F. G. Stevens, Esq., Bristol; G. B. Butter, Esq., Pill; and Thomas C. Parsons, Esq., Bristol.

Papers.—The following papers were read:

1. Midwifery Notes. By J. S. BARTUM, Esq. Dr. Swayne and Mr. R. N. Stone made remarks.

2. A Case of Acute Rheumatism with Pericarditis. By W. H. SPENCER, M.D. This led to remarks from Drs. Goodridge, E. L. Fox, and Thompson.

3. On Urohematuria. By J. K. SPENDER, M.D. He related how a perfectly pale, almost colourless, urine might be the unsuspected vehicle of blood, robbing the body to a not less certain and damaging extent than if it displayed itself as ordinary blood in the usual way. Exhibiting no danger-signals to either doctor or patient, this treacherous and seemingly innocent urine might contain every element of destruction, and might represent wear and waste of a most fatal kind. The knowledge of this clinical condition was due to the sagacity of Dr. George Harley, who described it more than ten years ago. It frequently accompanied chlorosis, and could be demonstrated in the following way. The specific gravity was seldom below the standard, but if to a sample of the urine (which might contain no sugar or albumen) strong hydro-

chloric acid were added, a port-wine tint would be rapidly assumed, showing that there was an excess of combined urohæmatine, which was liberated by the acid. Consequently, there might be an immense destruction of blood-corpuscles in the body, and their *débris* be so eliminated as to be invisible until the application of an acid set it free. In these cases, the urine never contained blood-corpuscles. It was always alarming when the liberal administration of iron did not alter the urine, or hinder the excretion of metamorphosed blood; but Dr. Spender had found Dr. Harley's description literally true in so many cases during the last ten years, that he thought it might be an advantage to bring the matter under the notice of his medical friends.

SOUTH-EASTERN BRANCH: EAST KENT DISTRICT.

THE fifty-fourth meeting was held at the Library of the County Hospital, Canterbury, on November 19th; JOHN BOWES, Esq., in the chair. Twenty members were present.

FRANCIS BARTON, Esq., of Dover, was unanimously chosen as Chairman of the next meeting at Dover on March 18th.

Papers.—Mr. LONG read a case of Congenital Scrotal Hernia in a labourer, aged 30, becoming strangulated. At the operation, the hernia was found to consist entirely of omentum, which was tied and removed. The symptoms were unrelieved; and, after further explorations, the man died eighty hours after the operation. A *post mortem* examination revealed an internal strangulation of small intestines by the band of omentum which formed the hernia passing over it. In this piece of intestine there was a deep sulcus reducing its calibre by one-half, caused by omentum always lying across it; this was now found tightly constricted, and purplish black in colour.

2. Mr. LEWIS read a case of Facial Paralysis from Syphilitic Disease of the Temporal Bone. On *post mortem* examination, a tumour of the dura mater was found, being on the inner surface of the temporal bone.

3. Dr. WALLICH read a communication on some of the Properties and Effects of Chloral Hydrate. The author drew attention to the fact that the conflicting results which had, from time to time, been attributed to chloral hydrate, and had induced some persons to condemn it as a drug both uncertain and unsafe in its action, were due in all probability to the marked diversities to be met with in the external characters, and even in the chemical constitution of the substance, as shown by the different formulæ which have been published for it. Chloral hydrate occurred either in massive tablets of varying thickness, or in small detached crystals. The latter of these two forms gave off no pungent or acrid fumes; was always more or less deliquescent; and was very largely soluble in plain water. The former gave off pungent fumes, which were in some samples acrid and acid, resembling those of hydrochloric acid, and like them visible to the eye, and was less readily soluble in water. According to the author's experience, the first named of these two forms never produced any of the deleterious effects complained of, even in cases where large doses had been persistently given, and the use of the drug continued for a protracted period. Regarding chloral hydrate as an unequalled sedative and hypnotic, and indirectly as an anodyne and anæsthetic, Dr. Wallich maintained that, by due care in the selection of the drug, by never administering it on an empty stomach, by diluting it to a sufficient extent, and not merely covering the taste by syrups or other media, and, lastly, by giving it in moderate doses—from fifteen to thirty grains—repeated as circumstances demand, rather than in larger single doses, all its normal and beneficial effects might with certainty be secured. Where increased heart's action was the primary effect produced on the system, the author contended that either the drug itself or the mode of administration had been faulty.

Dinner.—The members afterwards dined together at the Fleur-de-Lis Hotel.

BIRMINGHAM AND MIDLAND COUNTIES BRANCH: ORDINARY MEETING.

THE second ordinary general meeting of the Session was held on Nov. 12th, at the Midland Institute, Birmingham, W. C. GARMAN, Esq., President, in the chair, when there were present fifty-nine members and visitors.

New Members.—Mr. T. J. Hawthorn, Oaken, Wolverhampton; Mr. Thomas Evans, M.B., Edinburgh; Dr. Ingleby McKenzie, Rugby; Mr. W. H. Meredith, Netterton; and Mr. Messeter and Dr. Wilson of Birmingham, were elected members of the Branch.

Testimonial to the late Honorary Secretary.—Mr. J. MANLEY proposed, and Dr. J. RUSSELL seconded, the following resolution: "That, in consideration of the services rendered to the Branch by the late Secretary, Mr. Bartleet, during a period of nine years, a testimonial be

presented to him; subscriptions not to exceed half-a-guinea." Mr. OLIVER PEMBERTON moved, and Mr. J. F. WEST seconded, the following amendment: "That, inasmuch as the position of Secretary to this Branch is an appointment of great professional advantage and distinction, it is undesirable to mark the retirement of such an officer by a testimonial solicited from its members." After some discussion, the amendment was put, and declared by the President to be lost. The original resolution was then carried. It was resolved, on the motion of Mr. MANLEY, seconded by Dr. RUSSELL: "That the following members of the Branch do form a Committee, with power to add to their number, for the purpose of carrying out the foregoing resolution—viz., Mr. Manley, Dr. Russell, Mr. Alfred Baker, Dr. Harrison, Mr. J. C. Gusman, Dr. Malins, and Dr. Bodington."

Communications.—Mr. LAWSON TAIT showed a specimen of Interstitial Tumour of the Uterus, which was provided with a very distinct and easily separated capsule, so that it would have been a very good case for the operation recommended by Dr. Marion Sims. The naked eye appearances were those of ordinary fibromyoma; but, on microscopic examination, it presented some curious cell-territories which were the subject of doubt. They might be an indication of commencing malignant proliferation, but Mr. Tait having seen the same characters exhibited by his new staining process in many other tumours which did not present any clinical evidence of cancerous change, he was inclined to regard these appearances as explanatory of the method of growth of these tumours, the more as they occurred in the neighbourhood of the blood-vessels. He had been able to inject the tumour very successfully, and to obtain evidence that the blood-vessels were very sparse; a fact which no doubt explained the readiness with which these tumours separate after injury to their capsules.

2. Dr. A. UNDERHILL narrated a case of Naso-Pharyngeal Polypus, with hypertrophy of the mucous membrane, for which tracheotomy and removal of the superior maxillary bone had been performed.

3. Mr. WEST read a paper entitled Recent Surgical Experience of the Hospitals of Germany, France, and Belgium. He passed in review the treatment of wounds, and the method of dealing with fractures, as seen in these hospitals; and also called attention to the existence or otherwise of pyæmia or erysipelas in relation to their size, age, and sanitary condition. Mr. West then brought forward various new instruments and pharmaceutical preparations which he had seen in use on the continent, and which seemed worthy of trial, and, in some instances of adoption, in the surgical practice of this country.

SOUTH-EASTERN BRANCH: WEST SUSSEX DISTRICT.

THE second meeting of the year was held at the board-room of the Infirmary, Chichester, on Tuesday, October 27th; Dr. TYACKE in the Chair; eleven other members being present.

Next Meeting.—It was unanimously resolved that the next meeting should be held at Horsham; and that Mr. Greenwood, of Two Mile Ash, be requested to act as Chairman.

Communications.—The following communications were then brought before the notice of the members present.

1. Dr. BUCKELL related the particulars of a case of Pharyngeal Fistula, and exhibited the patient.

2. Dr. ROBINSON related the particulars of a somewhat similar case.

3. Dr. WITHERS MOORE, at the request of the Chairman, related his experience of, and gave his opinion upon, the treatment of Hydrophobia.

All these communications gave rise to considerable discussion.

New Members.—Two gentlemen were proposed as members of the Association and the Branch.

The Dinner took place at the Dolphin Hotel, where fourteen gentlemen, including four visitors, assembled, under the presidency of Dr. Tyacke.

SOUTH-EASTERN BRANCH: WEST KENT DISTRICT.

THE second meeting of the eighteenth session, 1874-5, was held at Maidstone, on November 20th; H. CECIL SMITH, Esq., in the Chair.

The next meeting was appointed to be held at Gravesend in March or April, and Dr. Gramshaw was chosen Chairman.

New Members.—James Stewart, L.R.C.P., Barming Heath Asylum, a member of the Association, was elected a member of the Branch; Egbert Charlton, M.D., 17, Norfolk Street, London, and Doyle M. Shaw, L.R.C.S. Edin., Staff-Surgeon R.N., H.M.S. *Pembroke*, Chatham, were elected members of the Association; and W. Phillips Kirkman, M.D., of Barming Asylum, Maidstone, and William Fear, M.R.C.S.E., Brenchley, were elected members of the Association and Branch.

Papers, etc.—1. A clinical lecture was given by M. A. ADAMS, Esq., on a case of Astigmatism.

2. A paper was read by Dr. STEPHEN MONCKTON, on Acute Rheumatism changing into Pyæmia. The object of the paper was to show, chiefly by the citation of two well marked cases, that pyæmia occasionally proceeds directly out of rheumatic fever, the progress of the latter assuming a perverted and malignant course. That a case pyæmia from the first may for a time put on the semblance of rheumatism, and that rheumatic fever in a feeble subject may, though very rarely, lead to a fatal issue with typhoid symptoms, was admitted at once. But more than this was affirmed; the contention being, that genuine rheumatic fever in a subject of average power, and without pernicious surroundings, may, and in these two cases did, abruptly alter its course in such wise that the development of lactic acid ceases, and blood-poisoning with collapse, hæmorrhages, gland-swelling, icteric hue, and almost certain death, succeed. A case, therefore, may die pyæmic, and yet have been correctly diagnosed as rheumatic at the outset: just as a patient may succumb to purpura and universal hæmorrhages, who had been seized with small-pox to begin with: except that, in the former case, the primary disease will have been replaced by the secondary, instead of aggravated by it. Dr. Monckton suggested that too active saturation with alkalis might have mischievous tendencies in this direction; as also the undue exclusion of oxygen from anxiety to keep the patient warm. In neither of the cases quoted was there any evidence of erysipelas, purulent or septic contamination from without, fibrinous concretion, or ulcerative endocarditis. The mischief seemed to arise from a perversion of the chemical blood-change: the production, effects, and elimination of lactic acid ceasing, and toxæmia of a more disintegrating and deadly character replacing it. It may be remembered, that pyæmia has been produced by the artificial introduction of lactic acid into the blood.

3. Dr. ALLFREY related a case of Typhoid Fever succeeded by Rheumatic Fever with Pleurisy.

Dinner.—The members and visitors dined at the Mitre Hotel.

SOUTH WALES AND MONMOUTHSHIRE BRANCH: AUTUMNAL MEETING.

THE autumnal meeting of this Branch was held at the Black Lion Hotel, Aberdare, on November 26th, at 1 P.M.; present, W. T. EDWARDS, M.D. (Cardiff), President, in the Chair, and about thirty members.

New Members.—H. T. Pringle, M.D., County Asylum, Bridgend; L. G. Leslie, Esq., Saundersfoot; and T. G. Jones, Esq., Hirwaun, were elected members of the Association and Branch.

Papers, etc.—1. Mr. T. J. DYKE (Merthyr) explained and demonstrated Mr. Horsley's ready methods of detecting (1) Nitrates and Nitrites in Water, (2) Alum in Bread and Flour, (3) Water added to Milk and Cream abstracted, (4) Lard or Meat Fat in Butter.

2. Mr. EVAN JONES (Aberdare) read a few notes on Some of the Causes of Infant Mortality.

Public Health.—A Committee, formed for the purpose of "watching matters relating to public health" (Mr. E. R. Morgan, Neath, Honorary Secretary), considered the subject of statistical returns; and it was decided that the mode of returns used by the Registrar-General be adopted in the forthcoming annual report. Several officers of health complained of the lax and imperfect manner in which certificates of death were often filled up. The meeting was of opinion that these certificates should be sent direct by the medical man to the registrar, and not be given into the hands of a third party.

Next Meeting.—It was decided that the spring meeting should be held at Britonferry.

CORRESPONDENCE.

THE BRITISH MEDICAL ASSOCIATION: HONOURS TO THE PUBLIC SERVICES.

SIR,—I read with much pleasure the obituary notice on the late Sir Ranald Martin in your JOURNAL of the 19th December. It is far from my purpose to attempt to detract anything from the well merited eulogies accorded to him therein; but a sense of justice leads me to put you in possession of certain facts with reference to the grant of military honours to the medical officers of the army and navy. I do this in order that the zeal and important services of Mr. W. P. Brookes of Wenlock, and of the British Medical Association, in this matter, should not be overlooked. Sometime since I had an opportunity of reading the correspondence of

that gentleman with the Duke of Richmond, Lord Gough, Sir Howard Douglas, Sir De Lacy Evans, Gen. Herbert Edwards, Mr. G. J. Guthrie, Sir James MacGrigor, Sir W. Burnett, and Sir Ranald Martin himself, on the right of army and navy surgeons to military honours; from which it is evident that the advocacy of Sir Howard Douglas and Sir De Lacy Evans in Parliament, at the instance of Sir Ranald Martin, was not successful in obtaining the boon solicited from Her Majesty's Government. Indeed, in one of his letters to Mr. Brookes, Sir De Lacy Evans states that he regrets that his advocacy had not been successful.

It was thus intimated to certain medical officers of the Army and Navy that it was the intention of Her Majesty's Government to confer upon them certain decorations of the civil order of the Bath. Amongst others, such an intimation was conveyed to the late Mr. Guthrie, who declined the proffered honour.

At this stage of the proceedings, Mr. Brookes, who was then President of the Shropshire Branch of the British Medical Association, called the attention of the Branch to the subject; and forwarded, first, a memorial from himself to Sir George Grey (then Home Secretary), and afterwards one from the above-named Branch; he was also instrumental in obtaining similar memorials from Bath, Manchester, Liverpool, and other Branches of the Association. He was afterwards appointed to deliver an address on the services of the Army and Navy surgeons of the Queen's and Honourable East India Company's services, and to draw up a memorial to Lord John Russell on the subject, at the General Meeting of the Association held at Hull in 1850. The prayer of the memorial was soon after granted by Lord John Russell.

I think that it will be evident from the above brief summary of facts that the much-coveted and well-deserved honour was not granted until Sir Howard Douglas and Sir De Lacy Evans had failed; and that the ultimate success of the application was in great measure due to the efforts of Mr. W. P. Brookes, then President of the Shropshire Branch of the British Medical Association.

I am, Sir, your obedient Servant,

ERNEST TYLER SMITH, B.A., L.R.C.P.

BODY-FORCE AND STIMULANTS.

SIR,—I have read with much satisfaction your article upon "Body-force and Stimulation". I believe its teaching to be essentially sound. In my student days, I had the advantage of seeing the stimulant plan of treatment carried out to extremes by that excellent clinical teacher the late Dr. Todd and his disciples; and I saw it practised with more judicious moderation at Edinburgh under Dr. Hughes Bennett. I have since for eleven years been actively engaged in club, parish, and private practice, and have formed a very distinct opinion that the practice of indiscriminate feeding and stimulation now so much in vogue is injurious. Much of the success which I have had in the treatment of acute disease may have been the result of good fortune; but, to a large extent, I am convinced that it has been due to a recognition of the error in question. I have depended mainly upon milk, supplemented only by beef-tea; and, although I have had but few cases in which alcohol has not appeared to have been of service, I have given it in very moderate doses. I have generally found a teaspoonful, or at most a tablespoonful, of wine, given in a state of dilution and at regular intervals, more beneficial than larger quantities of wine or brandy. In the case of delicate children, when stimulants have appeared to me to be indicated, I have generally found claret sufficient.

But is not only to say this that I write, but to express an opinion I have long held, that such articles as those to which I refer—all in fact which treat dogmatically purely medical subjects—should bear the writer's name. The article in question bears great intrinsic evidence of merit, but I cannot help thinking that it would carry more weight, and be more generally useful to the profession, if we knew who was responsible for the opinions expressed. My remarks are of course not intended to apply to leading articles upon subjects of general professional polity.—I am, etc., C. H. ALLFREY, M.D., F.R.C.S. (exam.)

St. Mary Cray, December 14th, 1874.

MILITARY AND NAVAL MEDICAL SERVICES.

IT is confidently rumoured that the appellation of Staff-Surgeons of the Second Class will very shortly disappear from the *Navy List*.

MOVEMENTS OF ARMY MEDICAL OFFICERS.—Surgeon-Major A. W. Beveridge, 78th Highlanders, has been directed to take medical charge of the 1st Battalion Royal Welsh Fusiliers, at Aldershot, until further orders.—Surgeon Duke Park has been taken on the strength of the

Aldershot Division, and posted for duty to the 3rd Station Hospital.—Surgeon-Major W. Orr has been detailed to perform medical duties in connection with the 1st Station Hospital, Aldershot.—The following officers have arrived in India for duty, viz.: Surgeon-Major J. D. Saintes, and Surgeons J. L. Corbett, C. J. Warden, J. N. O'Keefe, L. Wood, M.D., W. Gubbins, M.D., B. Jago, M.D., J. Pendergast, J. A. Smith, J. Martin, J. Foss, M.D., and C. P. Turner.—Surgeon-Major Murphy has been ordered to proceed from Chatham to Dublin, for duty early in the year.—Staff-Surgeon Major J. Warren has been appointed to the medical charge of the 15th Hussars, *vice* Surgeon-Major Stewart.

STAFF-SURGEON J. P. BOILEAU, M.D., has been admitted a Diplomat in State Medicine of the University of Dublin. At the recent examination for the diploma, which embraced the subjects of Medical Jurisprudence, Law, Hygiene, Chemistry, Meteorology, Vital Statistics, Pathology, and State Medicine, Dr. Boileau obtained first place. Dr. Boileau entered the Army September 30th, 1864.

INSPECTOR-GENERAL of Hospitals and Fleets, John Davidson, C.B., M.D., who lately retired from active service, has been awarded, in addition to his pay, a pension of £400 *per annum*, in consideration of the frightful character of a disease with which he became infected while in the discharge of his professional duties.

OBITUARY.

FRANCIS KIERNAN, F.R.S.

THIS distinguished anatomist died at his residence in Manchester Street, Manchester Square, on Thursday last, December 31st, in his seventy-fifth year. He was born in Ireland on October 2nd, 1800. His father, who was a member of the London College of Surgeons, had four children, of whom Francis Kiernan was the eldest. At an early age his parents came to reside in England, and he was soon after sent to a college in Hertfordshire, where, by his great assiduity and his perseverance in the pursuit of knowledge, he laid the foundations of those successes which attended his future career.

Soon after leaving college, he entered at St. Bartholomew's Hospital, and threw himself, with his wonted enthusiasm, into the study of anatomy, of which he was most passionately fond. He speedily distinguished himself in this branch of his profession, and so great was his reputation, that students from all parts flocked to his private demonstrations in Charterhouse Square. Kiernan's great success as a teacher caused much jealousy, and, in 1825, gave rise to the Council of the College of Surgeons passing a resolution refusing to receive certificates from any but recognised teachers. This was a heavy blow to Kiernan's future prospects; the large class in Charterhouse Square rapidly decreased, as many of the students were unable to pay the fees to both the hospital and to a private teacher. He petitioned the Council to rescind their regulation. His application was backed by a strong testimonial, signed by Vincent, Lawrence, and Lloyd, surgeons to St. Bartholomew's Hospital, stating that the advantages he had derived from having devoted himself to the cultivation of anatomy and surgery in the most celebrated schools of France and Italy, rendered him, in their opinion, in all respects well qualified to act as a teacher, and, therefore, strongly recommended him to the favourable attention of the Court of Examiners. His request, however, was not granted.*

In November 1825, he was admitted a member of the Royal College of Surgeons. It was about this time that he commenced a series of minute investigations which led to those wonderful discoveries concerning the anatomy and physiology of the liver, with which his name will be for ever associated. The fame of these discoveries rapidly spread throughout Europe, and numerous were the visitors from all parts of the continent to his private museum to examine his microscopical preparations of the liver. His readiness to afford every information to all comers, resulted in a somewhat unpleasant incident. A Frenchman, having obtained from Kiernan all the information he could, returned to Paris, and had the audacity shortly after to publish Kiernan's discoveries as the result of his own investigations. This led to a long and tedious correspondence, which ended in proving that the Frenchman had no right to the laurels he had so unjustly tried to pluck from Kiernan's brow. The result of his labours he published, first of

all in the *Philosophical Transactions*, and afterwards in a separate work, entitled *Anatomical Researches into the Structure of the Liver*; for this he was rewarded by at once being elected a Fellow of the Royal Society, and soon afterwards, the additional honour of the award of the Copley Medal was conferred upon him—a distinction which is only bestowed upon men of singular merit.

In 1837, the University of London was incorporated by Royal Charter. Kiernan's name, owing to the active part he had taken in its formation, was associated with those to whom the Charter was given; he, therefore, became a member of the Senate, and was soon afterwards elected one of the Examiners in Anatomy and Physiology, an office which he continued to hold for many years.

In 1850, he was elected by the Fellows to a seat in the Council of the Royal College of Surgeons of England, an honour which was repeated at the termination of three successive quinquennial periods. About this time, he was overtaken by a severe illness, which confined him to the house for several months. His intimate friends, Messrs. Hodgson, Skey, and Stanley, were most unremitting in their kindness and attention. Stanley operated upon his leg, and removed a portion of the tibia, which had become diseased, the result of an accident in his schoolboy days. He was invited by the President of the College, in 1860, to deliver the Hunterian Oration in the following year; but, owing to the great aversion he felt to speak in public, he declined the honour. It was not until 1862, that Kiernan was elected a Member of the Court of Examiners. He succeeded Mr. Stanley, who died suddenly whilst going his rounds in the wards of St. Bartholomew's Hospital. As an examiner, Kiernan was most just and impartial.

In July 1864, he was elected one of the Vice-Presidents of the College; and in January 1865 he was seized with a paralytic stroke, from the effects of which he, however, partially recovered, but his speech remained impaired during the remainder of his life. In 1867, the five years having expired for which he was elected an Examiner in 1862, he declined, owing to the state of his health, to be again put in nomination for re-election. Thus was severed Kiernan's connection with the College; but he ever took the warmest interest in its affairs, and only recently sent the whole of his collection to enrich the Hunterian Museum.

Kiernan was an ardent admirer of art, a taste for which he had no doubt imbibed during his early travels in Greece and Italy. His collection of sacred prints from the old masters, amounting to a very large number, obtained with infinite labour and at a great expense, was very large and valuable. This collection, when "putting his house in order" a few months since, he presented to an amiable and most accomplished nephew. His collection of portraits he presented to his friend and medical attendant Mr. Edwin Sass, from whom he received unremitting attention.

EDMUND SNELL, L.R.C.P.E.D.

THE late Edmund Snell was a native of Cornwall. Having received his early education in that county, he came to London, and studied at Charing Cross Hospital and the Charlotte Street School of Medicine from 1841 to 1845. Having obtained his diploma, he returned to his native part, and practised there for a short time; but, wishing to settle in London, he came to Mile End, and took the old established practice of the late Mr. G. E. Carruthers, and there practised for twenty-seven years. The deceased was a vestryman and guardian of Mile End. He died October 26th, at the early age of fifty-three, leaving a wife and son.

WILLIAM HARGRAVE, M.B., F.R.C.S.I.

THIS member of our profession died, at the advanced age of 79, on November 24th, at his residence in Upper Mount Street, Dublin. Born at Cork in 1797, he graduated at the University of Dublin, and was apprenticed to the late Sir Philip Crampton. Having obtained his surgical degree, he visited Paris, where he studied under Dupuytren and Laennec, and travelled through Germany, Switzerland, Italy, and Greece. After some years' practice in Dublin, he was appointed Lecturer on Anatomy in the school attached to the Royal College of Surgeons, which post he resigned after some time, and was elected to the Professorship of Surgery in the same institution, which he held until increasing years obliged him to retire. He was an ex-president of the College of Surgeons, and a representative in the General Medical Council for several years, also Surgeon to the City of Dublin Hospital. He was a sincere and upright man, and will be remembered as a skilful surgeon and true friend. He was the author of *A System of Operative Surgery*, and contributed several papers to medical journals, among others, one on Deligation of the Left Common Iliac Artery—the first successful case operated on in Ireland. His remains were interred in the family burial-place at Naas. The funeral was attended by the

* The reader is referred to the celebrated speeches of Mr. (afterwards Sir William) Lawrence, respecting the treatment of Mr. Kiernan and others, by the Council of the Royal College of Surgeons.

leading members of the profession, and a band of students from the school of the College of Surgeons walked in procession for a considerable distance.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, December 17th, 1874.

Cassan, Theodore, County Asylum, Gloucester
Spark, Sidney Walter, 31, Myddelton Square, N.
Watts, Fred, Plymouth

The following gentleman also on the same day passed his primary professional examination.

Taylor, Henry Edward, Leeds School of Medicine

The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, December 24th, 1874.

Bailey, Samuel Henry, Nottingham
Favell, Richard, Sheffield
Homan, George William, King's College Hospital
Lewis, David Howell, Brechfa, near Carmarthen
Theed, William Cawood, Barkham, Wokingham, Berks

The following gentlemen also on the same day passed their primary professional examination.

Bevan, Richard, Guy's Hospital
Bruce, Robert, St. Bartholomew's Hospital
Cambridge, Thomas Arthur, Middlesex Hospital
Clements, William George, Middlesex Hospital
Collingridge, William, St. Bartholomew's Hospital
Fell, Thomas Kennedy, Guy's Hospital
Knight, John Tomlinson, Guy's Hospital
Manders, Horace, St. Mary's Hospital
Townsend, Charles Percy G., Queen's Hospital, Birmingham

UNIVERSITY OF DUBLIN: SCHOOL OF PHYSIC IN IRELAND.—At the Michaelmas Term examinations in Medicine and Surgery, the following candidates passed, their names being arranged in the order of merit.—For the Degree of M.B.:

Hunter, William L.	Taaffe, Robert
Kellett, Leonard H.	Mason, Samuel R.
Hearn, Richard Thomas	Nickson, George M.
Farrell, Peter J.	Beakley, Alexander S.
Drummond, David	Blood, Matthew S.

For the Degree of M.Ch.:

Eaton, James B.	Murphy, George W.
Murray, Charles F.	Johnston, William
Drummond, David	

The examination for the Diploma in State Medicine took place on December 10th, 11th, and 12th, 1874. The following gentlemen were successful:

Boileau, J. P. H., M.D.	Tweedy, Henry J., M.D.
Woodhouse, Stewart, M.D.	

MEDICAL VACANCIES.

The following vacancies are announced:—

ABERYSTWYTH INFIRMARY—Surgeon.
ARMY MEDICAL DEPARTMENT—Surgeons. Applications to be made to the Director-General of the Army Medical Department.

ATHY UNION, co. Kildare—Medical Officer and Public Vaccinator. Salary, £120 and fees.

BALLACHULISH SLATE QUARRIES—Medical Officer. Salary, £200 per annum. Testimonials to be sent in to J. Gardner, Ballachulish, N.B., on or before the 14th instant.

BLACKBURN UNION—Medical Officer for the Harwood District. Salary, £25 per annum.

BLYTHFORD UNION—Medical Officer for No. 9 District. Salary, £39 per annum.

BRADFORD UNION—Medical Officer for the Workhouse. Salary, £225 per annum.

BRIDGWATER UNION—Medical Officer for No. 2 District. Salary, £70 per annum.

CASTLE WARD UNION—Medical Officer for the Ponteland District. Salary, £20 per annum. Also, the Workhouse. Salary, £10 per annum.

CITY ORTHOPEDIC HOSPITAL, Hatton Garden—Assistant-Surgeon. Applicants must be F. or M.R.C.S. Applications on or before January 2nd, 1875.

DERBYSHIRE GENERAL INFIRMARY—Assistant House Surgeon. Board, lodging, and washing, but no salary. Applications to Secretary.

EAST SUSSEX, HASTINGS, and ST. LEONARD'S INFIRMARY—Assistant-Surgeon.

ESSEX LUNATIC ASYLUM—Second Assistant Medical Officer and Dispenser. Salary, £100 per annum, with board, lodging, and washing.

FIFE AND KINROSS DISTRICT ASYLUM—Assistant Physicianship. Salary, £80, with board, etc. Apply to Dr. Fraser, Medical Superintendent, Cupar-Fife.

GREAT NORTHERN HOSPITAL, Caledonian Road—One Physician and one Surgeon. Applications to be sent in on or before January 14th, 1875.

GREENWICH UNION—Workhouse Medical Officer. Salary, £300 per annum. Applications on or before January 7th, 1875.

HARRIS, Parochial Board of—Surgeon. Salary, £66 per annum, including vaccination and medicine for the poor. The gentleman elected will get £90 per annum for attending the ratepayers and cottars within South Harris. Applications to be made to the Chairman of the Parochial Board of Harris.

HEADINGTON UNION—Medical Officer for the Wheatley District. Salary, £70 per annum.

HOSPITAL FOR WOMEN, Soho Square—Surgeon and Assistant-Physician. Applications on or before January 4th, 1875.

HUDDERSFIELD INFIRMARY—Junior House-Surgeon. Salary, £40 per annum, with board and washing. Applications on or before the 4th instant.

INDIAN MEDICAL SERVICE—Twenty appointments as Surgeon. Examination in February 1875.

LEEK UNION—Medical Officer for the Workhouse. Salary, £85 per annum.

LICHFIELD UNION—Medical Officer for the Alrewas District. Salary, £35 per annum.

LLANELLY UNION—Medical Officer and Public Vaccinator for the Kidwelly District. Salary, £20 per annum, and fees. Applications to be sent in on or before January 6th, 1875.

LOCHMABEN, Parish of, Dumfriesshire—Medical Officer. Salary, £50 per annum, and fees. Testimonials to be lodged with the Inspector of Poor on or before the 16th instant.

METROPOLITAN ASYLUM DISTRICT—Medical Superintendent of a temporary Asylum for Imbecile Children. Salary, £400 per annum, with furnished house, c. & gas. Applications on or before the 13th instant.

MIDDLESEX HOSPITAL—Surgical Registrar. Applications on or before January 8th, 1875.

MIDDLESEX LUNATIC ASYLUM, Hanwell—Assistant Medical Officer.

MITFORD and LAUNDITCH UNION—Medical Officer for the Workhouse. Salary, £45 per annum.

NORTH RIVERLY UNION—Medical Officer for the Seventh District.

NORTH-EASTERN HOSPITAL FOR SICK CHILDREN, Hackney Road, E.—House-Surgeon. Salary, £100 per annum, with attendance, rooms, coals and light.

NORTH WALES COUNTY LUNATIC ASYLUM—Assistant Medical Officer. Salary, £100 per annum, with board, lodging, and washing. Applications to be sent in on or before the 13th instant.

PLYMOUTH UNION—Medical Officer for No. 3 District.

QUEEN CHARLOTTE'S LYING IN HOSPITAL—House-Surgeon. Applications to be sent in on or before the 6th instant.

REDITCH and DISTRICT MEDICAL ASSOCIATION—Medical Officer. Salary, £150 per annum, with fees and unfurnished house.

RICHMOND (Surrey) UNION—Medical Officer for the Richmond District. £100 per annum.

RISBRIDGE UNION—Medical Officer for the Fourth District.

RYDE DISPENSARY—Physician.

ST. BARTHOLOMEW'S HOSPITAL—Assistant Physician.

ST. LUKE'S HOSPITAL FOR LUNATICS—Second Clinical Assistant. Board and furnished apartments.

SHEFFIELD PUBLIC HOSPITAL and DISPENSARY—House-Surgeon. Salary, £100 per annum, with board, lodging, gas, and washing.

SLEAFORD UNION—Medical Officer for the Sleaford District and the Workhouse. Salary, £50 and £30 per annum respectively.

SMALLBURGH UNION—Medical Officer for the Ludham District. Salary, £52.14 per annum.

STRATHKINNESS, Village and District of—Medical Officer. Salary, £10 from Parochial Board, with £110 from a workmen's club, exclusive of midwifery fees. Apply to Mr. A. Cowper, Kincaid, Cupar Fife.

SWANSEA URBAN and PORT SANITARY DISTRICT—Medical Officer of Health. Salary, £200 per annum, and fees.

TENDRING UNION—Medical Officer for the First and Second Districts. Salary, £97 per annum.

TORPHINS in the Parish of Kincardine O'Neil, Aberdeenshire—Parochial Medical Officer: £45 per annum. Applications to Chairman of Parochial Board.

TOWN'S HOSPITAL and ASYLUM, Glasgow—Medical Assistant. Salary, £80 per annum, with board and lodging. Applications on or before the 2nd instant.

TRINITY COLLEGE, Dublin—Professor of Chemistry: £500 per annum, and fees. Applications to the Rev. Dr. Haughton, Trinity College.

TYNEMOUTH UNION—Vaccination Officer.

UNIVERSITY OF EDINBURGH—Additional Examiner in Medicine.

WESTBOURNE PROVIDENT DISPENSARY and MATERNITY, Queen's Road, Bayswater—Surgeon. Applications on or before the 6th instant.

WHITBY DISTRICT LOCAL BOARD—Medical Officer of Health. Applications to be sent in on or before the 14th instant.

WOOLWICH UNION, Kent—Assistant Medical Officer to the new Infirmary at Plumstead. Salary, £60 per annum, with board, lodging, and washing. An additional salary of £20 per annum will be given for dispensing for the poor of the Plumstead District.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

BAKER, Benjamin R., M.R.C.S.Eng., appointed Second Clinical Assistant at St. Luke's Hospital for Lunatics.

HERAPATH, Charles K. C., M.R.C.S.Eng., appointed Surgeon to the Bristol Dispensary, Sixth District.

PLUMER, Charles J., M.D., appointed Assistant Physician to the Western Infirmary, Glasgow.

STRELL, Graham, M.B., appointed Medical Registrar to the London Fever Hospital.

STEELE, Wm. A., M.B., appointed Medical Registrar to the National Hospital for the Paralysed and Epileptic.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.

BIRTH.

GALTON.—On December 25th, 1874, at Woodside, Anerley Road, Upper Norwood, the wife of *John H. Galton, M.D., of a daughter.

OPERATION DAYS AT THE HOSPITALS.

- MONDAY**Metropolitan Free, 2 P.M.—St. Mark's, 6 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.
- TUESDAY**Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.
- WEDNESDAY** ..St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Drompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.
- THURSDAY**St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.
- FRIDAY**Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.
- SATURDAY**St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—East London Hospital for Children, 2 P.M.—Hospital for Women, 9.30 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M.—Royal Free, 9 A.M. and 2 P.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

- MONDAY**.—Medical Society of London, 8.30 P.M. Mr. C. F. Maunders: Lettsoman Lectures, "The Surgery of the Arteries (illustrated by twenty-seven Operations of Ligature by the author), and other Cases of Disease and Injury".
- TUESDAY**.—Pathological Society of London, 8 P.M. Annual Meeting for the election of Officers; Report; Address; etc. The following Preparations will also be exhibited. Mr. Lawson: Sarcoma of the sclerotic. Dr. Wickham Legg: Aneurism of Mitral Valve. Mr. Alex. Morison: Specimens of Urinary and Biliary Calculi. Mr. Sydney Jones: Congenital Dislocation of both Hips (a living subject); Large Lymphangioma secreting Chyle (a living subject); Hypertrophy of Limb from Disease of Knee joint (a living subject). Mr. Nunn: Hypertrophied Bursa Patellae removed by Operation; Epithelioma of the Colon. Mr. Bryant: Complete Cancerous Occlusion of the Rectum in a girl aged 18 years—Colotomy; Extreme Ulceration of the Rectum cured after Colotomy. Dr. Hoggan: Microscopical Specimen of Melanoid Sarcoma in a Cod-fish; Microscopical Specimens of Cancer prepared by a new Process. Dr. Way: Internal Stricture, with Rupture of Cæcum.
- WEDNESDAY**.—Obstetrical Society of London, 8 P.M. Annual Meeting; Election of Officers; President's Address. Dr. Bathurst Woodman, "On the Treatment of Mammary Abscess by Rest"; Dr. Madge, "On a Case of Labour complicated by Pelvic Tumour and by Convulsions"; Mr. Ashburton Thompson, "On Zinc Phosphate in Cases of Amenorrhæa".
- THURSDAY**.—Harveian Society of London, 8 P.M. Annual Meeting; Election of Officers; President's Address; Conversation.
- FRIDAY**.—Clinical Society of London, 8.30 P.M. Mr. Teevan, "A Case of Subcutaneous Urethrotomy"; Dr. Farquharson, "A Case of Hæmoptysis in a Syphilitic Patient"; Mr. T. Holmes, "A Case of Naso-pharyngeal Polypus".

NOTICES TO CORRESPONDENTS.

- CORRESPONDENTS** not answered, are requested to look to the Notices to Correspondents of the following week.
- PUBLIC HEALTH DEPARTMENT**.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with *Duplicate Copies*.
- AUTHORS** desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.
- CORRESPONDENTS**, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.
- WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.**
- COMMUNICATIONS** respecting editorial matters, should be addressed to the Editor: those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

VISITING LISTS.

We have received copies of Letts's Diaries. No. 45 is a very valuable table-diary for persons requiring space for a good deal of writing, for additional pages of writing paper are supplied. Letts's *Medical Diary* is a very excellent and complete pocket-book, especially suitable for the daily purposes of medical practice, having space for the entry of daily visits, accouchements, vaccinations, etc., and supplying a good deal of useful information.

Dr. SHEEN of Cardiff has made his little pocket visiting-lists more complete than they were last year, and still more handy.

Dr. T. H. BARTLEY (Baillière, Tindall, and Co.) has published an useful little *Posological Table of Medicine of the British Pharmacopæia*, which can be carried with visiting lists or medical diary by gentlemen of short memories.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

DISINFECTANT.—Our correspondent should apply to Dr. Fox, Cockermouth, for the information required.

MASTURBATION IN CHILDREN.

SIR.—I can thoroughly endorse the advice given by "M.R.C.S. Eng.", in last week's JOURNAL, on the above subject. He says, "Look after the child's nurse". I had a very shocking and distressing case a year or so ago, when a bright, intelligent little boy, about six years old, was taken into the bed of his nurse-girl every night, placed between her legs, and kept there more or less all night. After awhile, it came to the knowledge of his mother, and of course the nurse was instantly dismissed. But imagine her horror on finding that he afterwards got into the bed of a little sister about a year younger than himself, and did the same thing as with the nurse; and still later, when they were separated and carefully watched at night, he would seek an opportunity in the day-time and throw her down on the floor for the same purpose. His health of course suffered much, and at first his condition was a puzzle. He was sent away to school, in judicious hands, and he is now hearty and healthy, and seems to have entirely forgotten his former propensity. Therefore, I say, "Look after the nurse" in such cases, but especially the nurse-girl.

I am, etc.,

WILLIAM HOAR

Maidsstone, December 17th, 1874.

AN OLD MEMBER.—We have looked through the paper of Chemistry Questions at the preliminary examination of the Royal College of Surgeons of England. We are of opinion that they are correctly described as "elementary", and we can see no ground for complaint in respect to them.

THE WORTHING INFIRMARY.

SIR.—As you have brought my name forward in the JOURNAL in connection with the differences said to exist between the members of the staff of the Worthing Infirmary, I feel bound to ask you to allow me to state my views of the case, in order that I may stand in a proper light before my medical confidants.

Let me first of all say that I have no personal feeling whatever against Dr. Goldsmith in the matter: my wish is, that no change should take place in the number or respective positions of the present members of the staff of this infirmary, and the course I have pursued, although one of apparent opposition, is in reality dictated by a desire to retain Dr. Goldsmith's services in his present capacity.

Some few weeks back, Dr. Goldsmith requested his two colleagues to undertake the care of surgical in-patients during his month of office, to which proposition they agreed, upon the understanding that such agreement was a private and provisional one, and referred simply to in- and not to out-patients; but, in the course of a subsequent conversation, they understood from him, that he wished to give up the care of surgical out-patients as well, and he also made the following statement in writing: "It is my intention to give up the surgical part of the duties of the infirmary. If I can retain the medical part as physician, I shall be happy to do so, but if the committee decline to make such change, I shall place my resignation in the hands of the Governors, with the request that such an arrangement may be made."

The compact thus made, would have remained in force but for two reasons. 1st. Dr. Goldsmith, feeling that it might be said that he occupied a false position towards the Governors by undertaking duties which he did not intend for the future to perform, brought the subject before the Committee of Management; the affair thus ceased to be a purely private matter between the members of the staff. 2nd. Dr. Goldsmith made no secret of the fact that he aspired to become physician to the Infirmary, and that this was but the stepping-stone to his being appointed to that office, which at present does not exist.

The staff consists of three members, who take priority from the date of their appointment, but are otherwise upon the same footing, and perform similar duties, which are as follows: viz., to attend two days in the week to see out-patients, and to receive "in-patients" under their care month by month in rotation.

Without entering into the question, whether a member of the profession, who is a "general practitioner", can occupy the position of physician to a hospital or an Infirmary, it seems to me, in the present instance, that this proceeding on the part of Dr. Goldsmith is, to say the least of it, rather an arbitrary one. His proposition, had it been carried, would have completely altered the constitution and working of the institution, which the members of the Committee of Management, by their vote, do not consider at present desirable, or required in the interests of the institution.

My amendment, viz., "That no change be made in the present (not personal) status or position of the medical staff of this institution," was made purely from a view of ascertaining the wishes of the Committee, and, as I have said before, from no animus against Dr. Goldsmith; but I feel that he, being a "general practitioner", is not qualified to occupy the post of physician to any institution; and that, not only is such an appointment, as far as regards the Worthing Infirmary, unnecessary, but that any change whatever in the staff is at present undesirable.

During the time, now upwards of ten years, that I have been officially connected with the institution, no differences, as far as I am aware of, have existed between the members of the staff; and I am assured by the Honorary Secretary that, in spite of various changes, which of necessity have occurred from deaths and resignations, this harmonious state of things has always prevailed; and I consider it would be a great pity to disturb that good feeling and confidence between us which has hitherto existed, and which, in spite of this *contemps*, might continue.

I must apologise for the length of this communication, but some reply was absolutely necessary, and nothing less than what I have stated would have explained the other side of the question.

I am, Sir, yours obediently,

WM. J. HARRIS, M.R.C.S.E., L.S.A.,
Senior Medical Officer to the Worthing Infirmary.

13, Marine Parade, Worthing, December 26th, 1874.

* * * We very willingly publish Mr. Harris's letter. He does not impugn the facts contained in our article: for, he not only admits differences to exist, but points out where and how they exist. He even strengthens the case we made out in our last issue; for he plainly states that, if these differences are not amicably settled, Dr. Goldsmith will resign. We would further point out to Mr. Harris, the strong probability that the Committee of Management decided against the election of an honorary physician, because they naturally felt anxious to rally

round their senior medical officer and to support his views. We assure Mr. Harris he is in error in supposing that "a general practitioner is not qualified to occupy the post of physician to any institution". It is the rule at most of the small institutions, and at even some of the large provincial hospitals (the General Infirmary at Leeds, for instance), that a general practitioner is eligible to fill the office of honorary physician, provided he be a graduate of a British University and undertakes not to practise pharmacy. Under all the circumstances of the case, in the interests of the profession and the institution in question, we appeal to Mr. Harris to follow the course we suggested last week, and to recommend the Committee to pass a resolution to the effect, that the seniority of Mr. Harris be secured, and that Dr. Goldsmith be elected honorary physician. We confidently urge Mr. Harris to take this course, because the election of an honorary physician will insure that the six beds now available for medical cases are made to do all the work that they possibly can.

Sir,—I think your remarks concerning the Worthing Infirmary, in your last number, demand some observations from me.

You appear to have arrived at a very clear conception of the state of affairs; but, at the same time, some little explanation of my position may remove any erroneous impression that might be formed. I begin, therefore, by saying that some time since I mentioned to my colleagues, Messrs. Harris and Collet, that it had long been my wish to retire gradually from surgical work. As the Committee had determined to recommend the admission of medical in-patients, it struck me that a suitable opportunity presented itself to enable me to carry my purpose into effect. Finding that any alteration in the status of the staff was likely to be unacceptable to my colleagues, we mutually agreed that I should refrain from resignation on the condition that they would, between them, undertake the surgical in-cases occurring during the months allotted to me. Upon consideration, I felt myself in a false position with the Governors who had appointed me to fulfil certain duties, which I had just arranged not to carry out. I, therefore, proposed that the Committee of Management should sanction the private arrangement entered into between us, and wrote to this effect to my colleagues. Before putting any notice on the agenda, I showed it to Mr. Harris at the Infirmary, and explained what course I meant to pursue, adding "I presume you will support this". The only remark he made was, "Well, it may lead to some discussion". I then handed my notice to the assistant secretary. I took no steps to secure the attendance of any members of the Committee, as I expected no opposition. But, the moment I entered the committee room and saw who were there, I knew mischief was brewing; but I did not expect that, without any warning, I was to meet with unqualified opposition on the part of my colleagues. I stated at this meeting, that I merely wished the private agreement to be sanctioned by the Committee; but that my ulterior object and wish was, at some future time, to become physician to the institution. One of the members suggested that the medical staff should retire to see whether some mutual arrangement could not be arrived at. Then, and not until then, the real truth came out. Mr. Harris said, "As long as I am on the staff, whoever is appointed physician to this Infirmary, shall practise as a pure physician." I remarked, "That such restrictions were not usual in provincial infirmaries." He repeated, with the strongest emphasis, "He shall". Now, sir, I will leave you to judge of the propriety of these words from one member of the staff to another. In this particular case there are reasons why *three* is an inconvenient and undesirable number of medical officers; and, therefore, I think your suggestions offer the only satisfactory solution. At the present time, although the number of out patients and the amount of work are greater than they have ever been, the medical staff was never so numerically weak since the institution was established. There is ample scope for a physician and three surgeons. I have not the slightest wish to dictate to the Committee, nor indeed have I the right to do so; but it strikes me that, unless some such course as you suggest is adopted, no other alternative is left to me but to resign my appointment as surgeon, a step which would cause me much regret.

I am, Sir, your obedient servant, JOHN GOLDSMITH, M.D.

G. S. M.—We should think that the coroner's conduct was decidedly illegal. He was bound to allow the fee, having summoned the witness; and we think the fee could be recovered.

MEDICAL DEGREES AND TITLES.

Sir,—Let me thank you very sincerely for your article in Saturday's JOURNAL on "Medical Titles". I feel the present position of our Universities to be a disgrace to our age, and I think it is doing a real injury to the profession. A reform which would place a good M.D. degree open to men who could pass a good sound examination would prevent the present rage for sham or shabby substitutes, and save the profession the degradation of more "years of grace".

My hearty thanks for your outspoken and able article. I hope it will begin the destruction of the present monopoly system. I am, etc.,

December 1874.

M.D., BIRMINGHAM.

Sir,—In continuation of the controversy regarding medical degrees and titles, I should very much like to put a few general questions to some of our M.D. adversaries. I say some advisedly, as I am pretty sure that the number of those gentlemen who are agitating themselves on the subject represents but a small minority of their *confre*s similarly enrolled by that particular degree of M.D. As a licentiate of the King and Queen's College of Physicians in Ireland, I not only lay claim to the prefix of Dr., but I assert that I am a Doctor legally and morally. If I am not, what am I? True, I have not taken the University degree of M.D.; but what of that? It is not necessary to have that particular degree to be a doctor. The College of Physicians have, after an examination equal in severity and conducted by equally qualified men in every way to that for the University degree, legally declared me and my brother Licentiates to be physicians; and if physicians be not doctors, I do not know what doctors are. As Licentiates, we are entitled to write after our names, the initials of our degree, as M.D. men do; but we do not generally do so, for the simple reason of the inconvenient number of letters. I am also a Fellow of the College of Surgeons, and will any one challenge my right to the prefix "Surgeon"? I think not; and I submit with every consideration that the two cases are entirely synonymous. I grant that, speaking generally, men with the M.D. degree are, if anything, entitled to more consideration by reason of the longer time necessary, greater expense, and, if possible, higher curriculum to be passed before obtaining their degree; but I think they are amply rewarded by being enabled to sign after their names the two much coveted letters, which ought to be, and I think is, quite sufficient to distinguish them from their less honoured but otherwise equal brother practitioners. I trust that the number of those University men is few who, as such, consider them-

selves infinitely superior, professionally, to us simple Licentiates. Any Licentiate wrongly assuming the title of M.D., or any M.D. wrongly assuming the title of a Licentiate of a College of Physicians, ought to be proceeded against, for such symbols are the sole distinction between us; the broad fact remaining that, both being physicians, both are also doctors; and that has been on one notable occasion, at least, legally determined by an eminent judge, for the benefit of the King and Queen's College. I repeat, that the said College do not only profess, but are, moreover, legally and morally fully justified in endowing their members with such distinction.

I should like to know in what single way an M.D. man is more a Dr. than a Licentiate of a College of Physicians. I am not bigoted towards my own class; but I confess I cannot see, and, moreover, I should say there are very few M.D. men who do so either. If any change is to be made in the existing rules or customs in these matters, I think it should be to exclude University men from using the prefix "Dr.", reserving that for those who cannot use the initials M.D., as both together are manifestly unnecessary. Military or naval men do not require to go through an University to be entitled "Lieutenants"; and are such who do not any the less lieutenants than those who have passed from an University? I think not. If a gentleman serve an apprenticeship to, and obtain a certificate of competency from, an engineer, is he not an engineer? and, because he has not taken his C.E. from an University, is he not entitled to the prefix "Engineer"? I should think he was. Exactly so in our case; and how or why University men profess to deny such, I am at a loss to conceive. Perhaps some energetic M.D. may enlighten me on the subject, and prove to my satisfaction that I am not a doctor at all; if so, I will at once and for ever forego the title; and if I am not a doctor, neither am I a surgeon, and it will devolve upon him to tell me what I really am. Perhaps I am only a baker or a tinker after all. I should not be surprised if I were told so.

With every respect, I consider that the suggestion of your correspondent "Country Practitioner", with regard to praying some foreign University to send over examiners to examine and pronounce us M.D.s, would indeed be a disreputable proceeding, and ought to be summarily scouted. Any Licentiates who are so very much enamoured of the initials M.D., ought to be prepared to spend a certain time—at Edinburgh, for instance—and duly pass the required examination, and thus obtain the coveted honour in a respectable way.

Middlesex, Dec. 8th, 1874.

I am, etc.,

L. K. Q. C. P. I.

LEX (Lincoln's Inn).—We are afraid not. Something of the sort appeared in *The Daily Post* of December 29th, 1731, which published some proposals for castrating criminals, extracted from a pamphlet published in Ireland, showing that, if this plan were adopted and five hundred examples made, it would have such an influence upon the wicked, that our judges and juries would have much less business on their hands. The castration would cool the heat of those guilty of rape and sodomy; and, as theft and rapine often run in the blood, such a law would disable a set of vile people from leaving their pernicious breed behind them. Hector Boece affirms that the ancient Scots gelded such as laboured under madness or infectious distempers, which they thought might be communicated to their offspring.

REMARKS

ON THE

SYSTEMIC INDICATIONS OF CHRONIC
BRIGHT'S DISEASE.*By J. MILNER FOTHERGILL, M.D., M.R.C.P.L.,
Junior Physician to the West London Hospital, etc.

THE importance of the recognition of chronic renal disease will be admitted by everyone: it may, then, not be out of place to bring the matter before the notice of this influential gathering of medical men. The very able paper of Dr. Grainger Stewart, read at our last annual meeting, and the work of Dr. George Johnson recently published, have given to this subject a prominence which it distinctly merited. But, in a matter so complex, with sequels varying so much, according to the peculiarities of individuals, with manifestations so widely different, it is not easy to grasp the subject without applied and sustained attention to it; and, as many blows are required to fell an oak, so the vigorous reiteration of numerous individuals is necessary in order to place the subject of the consequences of chronic renal disease, commonly called "suppressed gout", before the medical public in an intelligible and comprehensible manner.

To-day, I propose to exclude from our consideration the effects of chronic renal disease upon the urine itself, designedly to avoid the questions of albuminuria and tube-casts. On these matters, we all know more or less, and have our own opinions. I would rather draw attention to the effects produced upon the system generally by renal inadequacy, by imperfect kidney-action—of a blood laden with the products of retrograde tissue-metamorphosis, or of peptones which have never been converted into tissue. What I aspire to do, is to furnish the material for the formation of a strong presumptive diagnosis of the presence of renal disease when it is not possible, or not convenient, to make a thorough examination of the renal secretion. It is obvious that there are many circumstances under which such examination is impracticable; and no other than a thorough examination is trustworthy. It also happens that albumen is not uncommonly absent even in marked renal disease, and especially in the commonest of all forms, that in which we are now most interested, namely, the granular kidney; while tube-casts, especially in this form, are only to be found after patient, elaborate, and painstaking examination of the urine; and such investigation is simply impossible in the majority of the cases attending our out-patients' rooms, and even in a large proportion of the cases which the general practitioner is called upon to treat in his every-day practice.

Are there, then, any general indications, any ready means, of forming a presumptive diagnosis at least, of these cases, which the medical man can have ever at hand, and can apply to every case with which he is brought into contact? I am fully persuaded that there are. But do not mistake me: the matter is but yet in its infancy, there are also sources of fallacy; and what is put before you to-day is no more than what I have been able so far to gather. A further series of observations may, and probably will, add new facts, will winnow and sift what has been already collected. If each gentleman who forms a part of my audience to-day will only keep these cautions clearly before his mental vision, it will be easier for me to say what I have to tell.

In the first place, we may review the changes inaugurated in the circulation by chronic renal disease, not so much as consequences as almost a part of the disease. We might as well leave the effects upon the throat out of the consideration of scarlatina, as the effects upon the circulation out of the consideration of Bright's disease. Without alluding to any controversies, I will confine myself to the enumeration of the changes so induced as given by George Johnson and Traube. When the blood is imperfectly depurated by the kidneys, and the aid given by the skin and other auxiliaries is not sufficient to supplement that imperfect action of the kidneys, the products of tissue-waste and of superfluous peptones accumulate in the blood. The effect of the excess of waste products in the blood is to induce spasm of the muscular coat of the tiny arterioles of the system generally. This produces an obstruction to the flow forward of the arterial blood, and a rise in the blood-pressure. This was well shown in a paper which recently appeared in

the BRITISH MEDICAL JOURNAL, by Mr. Mahomed of the London Fever Hospital. The heightened blood-pressure, or increased arterial tension, offers a great resistance to the flow forward of the blood in the contraction of the left ventricle; and, as a consequence, hypertrophy of the left ventricle follows. We must dismiss from our minds any idea of antagonism betwixt the heart and the arterioles; such an idea would but obscure the subject, and create artificial difficulties. The excess of waste products induces spasm of the arterioles; this obstructs the blood-flow, and obstruction to the blood-flow, no matter how produced, induces hypertrophy of the heart. The matter in itself is clear enough, if not darkened by unfortunate explanations, which rather tend to shroud than illustrate the subject. The sustained spasm of the muscular coat of the arterioles eventuates in hypertrophy; so that we have an hypertrophied condition of the two muscular ends of the arterial system—the central muscular mass the heart, and the peripheral muscular tubes the arterioles. Betwixt these two hypertrophied muscular ends, the connecting tubes, the elastic arteries, are highly distended.

The condition of heightened pressure in the elastic arteries leads to various sequels, not only pathologically interesting, but diagnostically useful. Thus, we get an accentuation of the second sound of the heart, or, to be more exact, of the sound produced by the closure of the aortic valves. These valves are closed by the recoil of the elastic arteries, and especially of the aorta. Now, elastic bodies recoil in direct proportion to the amount of distension to which they have been subjected. Consequently, the arteries, over-distended in this condition, recoil with proportionate force, and so close the aortic valves with much violence, producing a louder note. This accentuation of the aortic second sound is highly estimated in Germany as a physical sign of Bright's disease. It is really of much importance.

We are all aware that the filtration of fluid from the blood into the tubules of the kidney is very much affected by the blood-pressure; the greater the pressure of the blood the faster the flow, as seen in the rapid accumulation of urine after the free imbibition of fluids; the lower the blood-pressure, the slower the filtration through the thin-walled vessels of the glomeruli of the kidney, and the less the bulk of urine; as seen in the scanty urine of advanced heart-disease. In chronic Bright's disease there is a persistent condition of high arterial tension, and consequently there ought to be a large flow of urine. Clinically, we know that this is the actual state of matters. A large flow of pale-coloured urine of low specific gravity is one of the best marked evidences of chronic renal disease.

This is all simple enough, surely; but, nevertheless, the absence of a large flow of urine does not negative the presence of renal disease. In some patients, and especially in women, the effects upon the circulation vary from what has just been described, and, instead of hypertrophy of the left ventricle being induced by the obstruction offered to the blood-flow, dilatation is produced from the yielding of the heart-structure; consequently, there is not the increased arterial tension and the results thereof. Notably, there is not the increased bulk of urine which is found along with hypertrophy of the left ventricle. There is an absence of the hard incompressible pulse of high arterial tension, while palpitation is often present, indicating the inability of the ventricle to overcome the obstruction offered by the spasmodically contracted arterioles. Mistakes are commonly made in the diagnosis of Bright's disease in women, from these variations in the resultant vascular changes of that condition.

But what is more important still, the hypertrophy of the left ventricle, ordinarily found, in the course of time undergoes structural degeneration. The increased arterial tension leads to over-distension of the elastic arteries, and this over-distension (*Überspannung*) is the commonest cause of that change in the arterial coats known as atheroma. This change, called atheroma, is a parenchymatous inflammation of the arterial walls, which gradually alters their structure, and causes them to become less and less elastic. The aorta especially is affected; and, as the aortic recoil is the propelling power which drives the blood into the coronary arteries—the nutrient arteries of the heart itself—when that recoil is diminished by growing inelasticity, the blood-supply to the heart becomes insufficient, and the muscular structure undergoes fatty degeneration, or necrosis. This decay of the primitive muscular fibres cuts down the power of the heart, and with it the sustained high arterial tension. What then follows? The large flow of urine, characteristic of the earlier stages, gradually and silently passes into the small bulk of urine, indicative of heart-failure, as the condition of cardiac debility becomes superimposed upon the primitive condition of renal cirrhosis. This change in the bulk of urine is most lucidly pointed out by Sir William Jenner in some lectures published in 1865. I know no more valuable contribution to our knowledge of this matter than those lectures, which should be read, and carefully re-read, by all thinking practitioners. In time, then, as the changes in

* Read before the Medical Section at the Annual Meeting of the British Medical Association in Norwich, August 1874.

the heart-structures proceed, the large bulk of urine merges, by insensible gradations, into the scanty flow of heart-failure. This change is one that must never be forgotten, as misapprehensions may readily arise if this change be overlooked.

There are indications furnished by these changes in the arterial system which are diagnostically valuable. The overstretching of the elastic arteries, which occurs in chronic Bright's disease, is the cause of the atheromatous condition of the arteries generally found along with renal disease. This over-distension, as the cause of atheromatous changes, has been pointed out by Tzostakowski in Germany, and by Moxon, Clifford Allbutt, and myself in this country ("Strain, in its Relation to the Circulatory Organs," BRITISH MEDICAL JOURNAL, March 15th, 1873). Consequently, arterial degeneration is very common in chronic Bright's disease; and the elongation and tortuosity of the arteries produced by atheroma, or endarteritis deformans, are readily seen in the serpentine temporal arteries, and felt in the radial pulse. Hard, thickened, elongated and tortuous arteries, are very common in chronic Bright's disease, and ought always to put the practitioner on his guard as to his diagnosis.

The spasm of the arterioles, which, as we have seen, is one of the first links of the pathological chain which we have been describing, is pronounced in the vessels of the skin. Consequently, the skin is dry, inactive, and does not readily perspire. The spasm, and consequent hypertrophy of the cutaneous arterioles, render the action of diaphoretics in ordinary doses quite ineffective. Such a condition of the skin is very common amongst the subjects of chronic Bright's disease, and especially in men, and in women where the effects upon the circulation are pronounced. At other times, chiefly in those women in whom hypertrophy of the left ventricle is not so distinct, the skin presents the appearance of water being effused into it, underneath it rather, and into the meshes of the subcutaneous areolar tissue. It is very commonly apparent in fulness of the lower eyelids, and in the pale oedematous hands, which look as if they would fester if scratched. This condition is found in the adynamic forms of renal disease, chiefly in women with dilated hearts; and still more, if they drink more alcohol than is desirable.

At this point, we may leave the changes in the circulation. A word, however, as to the frequency of apoplexy in the subjects of Bright's disease. The high arterial tension maintained by the hypertrophied heart and arterioles commonly eventuates in the rupture of an artery in the head; especially if there be already existing arterial degeneration.

We will now review the abnormal changes inaugurated or instituted by renal inadequacy through the blood upon different organs, especially the eliminant organs. Experiment has established the presence of urea and of the earlier products of histolysis in the blood after ligature of the ureters, or extirpation of the kidneys (Oppler, Schottin, Perls, and Zalesky); and Garrod has demonstrated the presence of uric acid in the blood of the gouty. The presence of these products in the blood in excess produces various results. Among the commonest are changes in the hair. If the hair be fine, it usually falls from the vertex, and the circle left in time often grows grey at the temples. If the hair be strong and coarse, it does not fall out, but turns grey early and completely. At other times, very white hairs will be found scattered amidst hair of natural hue. Scores of observations made in the great dead-house of Vienna enable me to speak with much confidence as to the coexistence of these changes in the hair along with renal disease.

The eyes are very commonly affected; but the changes revealed by the ophthalmoscope do not come within the scope of this paper. The sight is often impaired, or the patient may see double. There is often, too, an arcus senilis, not rarely partial, and found only under the upper eyelid. It is not so much the blue sharply defined arcus of green old age as the yellow arcus with indistinct margins and a cloudy cornea—cloudy from fat-granules being scattered through its substance. This last is very commonly found with early and marked senile degeneration. The ear is worth observing. In young gouty subjects, it is usually high-coloured, swollen, and shining; sometimes the lobe is red, and full to glistening, so tense is the skin. At other times, the development of connective tissue is more sparing, and the ear, especially the lobe, is wrinkled and withered-looking, and the helix is studded with chalk stones.

The *tout ensemble* of each case is marked and readily recognisable by the eye which has learned to note and register these changes. In one man, there are a high-coloured face, grey hair, and glistening earlobes, with a fair *embonpoint*; in another, there are a wrinkled ear, a similar condition of the skin of the face, an arcus, a bald crown, and general leanness: in both, there will be found a distinctly tortuous temporal artery. In a third, you will find pallor, isolated grey hairs, a watery-looking eyelid, a hand bearing similar watery characteristics, muscular

tremulousness, and a wavering unsteady eye, with a morbid self-consciousness, and a suspicious readiness to inveigh against stimulants. Just look about among your lady patients over middle age; you will soon find the person I have last described. These are typical forms; but there are others besides these three.

In all forms, however, there will be found one characteristic: a mental one; viz., irritability—a symptom more constantly present than any other. Ask these different persons, when patients, if they feel themselves at times very irritable; easily put out by slight exciting causes; often with a distinct consciousness that there is an element of unreason present, which adds to their irritability; and they will all answer in the affirmative. The plethoric individual will be distinctly and markedly irascible; the second will be found irritable and anxious, and the third fidgety, capricious, and desponding. We will linger a moment over these mental symptoms, so constant, so suggestive, and yet somehow so little understood. The plethoric individual has a well sustained flow of arterial blood to his brain-cells, and he is quick, hasty, impetuous, and commonly explosive. His cerebral cells are well supplied with blood holding in solution renal salts, which act as irritants. We are all familiar with the gouty temper, as well as the gouty temperament. But at times this person will suffer from unaccountable depression, and an anxiety he cannot dismiss. The explanation of this we shall find to lie in spasm of the arterioles of the pia mater and the grey matter of the convolutions; and the cerebral anæmia tints his thoughts with unhappiness. In the second and third forms, depression, gloomy presentiments, and dark forebodings, are the prominent characteristics, and the irascibility is veiled by an overwhelming condition of sadness. In the third form, this mental wretchedness is commonly the causal origin of the taste for alcohol; it is the relief it affords to this groundless mental pain or misery which forms its chief allurements, its essential attracting force.

In all these forms, there will be found a certain amount of sleeplessness. It does not arise from pain; but the patients cannot catch sleep. The thoughts are active, but they run in a circle. After long thought, or rather train of thought, the original point of departure is reached once more. This is exhausting and irritating. It is not till far into morning that they can drop off. When they awake, the imperfectly rested brain is irritable, lacking in grasp, and deficient in power of concentration and endurance.

One curious symptom you will find almost always present; and that is, the patient gets up at night to make water. One gets up at one o'clock; another not till five. Whatever the explanation of this phenomenon—and I have none to offer—it is most constant.

When, then, you find a patient, especially at or over middle age, presenting the physiological indications given above, put the following questions. "Are you irritable, and easily perturbed in mind? Are you often sleepless—not from pain; but you cannot catch sleep? Do you get up at night to make water?" If these questions be answered in the affirmative, then there exists good ground for a presumptive diagnosis of chronic renal disease. If the patient be old and the circulation failing, put the last question thus: "You do not make so much water as you used to do. Do you get up at nights still to make water?" An intelligent look, half of inquiry and half of suspicion, will tell you of your hit, before the speech of the patient assures you of the correctness of your aim. Here the failure of the circulation has produced that change in the bulk of urine previously described.

Such are the ordinary systemic indications of chronic Bright's disease; and when they are found, a thorough examination of the urine is indicated. In hospitals, it is also desirable to corroborate the diagnosis still further by the sphygmograph. The square-headed tracing is characteristic, and instructive to students.

When, then, we find patients presenting more or fewer of the characteristics given above, and at the same time suffering from ailments which are the common sequelæ of an imperfectly depurated blood, our suspicions ought at once to be aroused. The ailments which follow in the train of chronic Bright's disease are commonly affections of serous membranes, of mucous membranes, and of the skin. The mucous membranes and the skin are eliminant excretory organs which aid and supplement the action of the kidneys, especially when defective. Over-action or apparent disease upon their part is a common outcome of blood-impurity from renal inadequacy; and this over-action is a compensatory change, rather than actual disease. In particular, the bronchial lining membrane is liable to undergo changes in the form of chronic bronchitis, especially when the cold of winter arrests the activity of the skin, and so deprives the system of the aid furnished by cutaneous action in supplementing the imperfect action of the kidneys. The cold, too, acts as an irritant to the air-tubes; and between the two we find the explanation of much of our winter-cough.

At other times, there is dyspepsia from the gastric juice being contaminated by the presence of waste products. Not unfrequently there is diarrhoea of an uremic character. So common, indeed, are alterations in the intestinal canal in chronic Bright's disease, that Treitz found changes in the bowels in no fewer than one hundred and seventy-five out of two hundred and two cases examined. The bowel is affected quite as much as a compensating excretory organ, as a sequel, a secondary consequence, of the kidney-mischief.

The skin is very frequently the seat of changes under the circumstances of chronic Bright's disease; more so, however, in those cases where the skin is active in compensatory functional activity, than in those cases where it is dry and inactive. The chronic eruptions of advanced life are ordinarily the result of renal mischief; and this is especially true of eczema.

At other times, there are affections of the serous membranes. These lymph-sacs are often irritated, or even inflamed, by the waste-laden lymph flowing through them. At other times, there is what is called muscular rheumatism, from the presence of waste material in the muscles. Very commonly, we find the joints infiltrated with waste matter, especially in the form of uric acid. This is gout proper.

Such are the common outcomes of a condition of blood arising from imperfect depuration by kidneys no longer in their pristine integrity. When, then, such states are found along with the physiognomical indications given above, and the various questions above related are answered in the affirmative, a strong presumptive diagnosis is furnished as to the presence of renal disease. This species of examination is feasible in every case, and can form part of the stock knowledge of the busiest practitioner. Often and often will he find most valuable information so furnished; giving a direction to his treatment, and guiding his therapeutic measures, in cases where he may not have the opportunity of making a careful examination of the urine. Variations in the bulk of urine—at one time a large flow of limpid urine, at another a lessened flow of dark dense urine—give information almost as valuable as that furnished by the urinometer and the test-tube. Finally, to these general indications may be added headache, chiefly vertical. This last objective symptom is commonly present in the adynamic forms of renal disease.

There is a peculiarity about those diseases which are the consequences of chronic Bright's disease, and that is their tendency to recurrence. Not that necessarily the same form of ailment is always assumed; the different consequences are interchangeable. Thus gout is interchangeable with bronchitis, with a skin-eruption, or with a troublesome dyspepsia. The common origin of each is further evidenced by the readiness with which each form will yield to remedial measures directed to the causal renal condition, while stubbornly resisting the measures which ordinarily are found curative. One very illustrative case will point these remarks usefully. A friend of mine once put to me the case of a patient with an obstinate irritable ulcer, which had resisted for eighteen years the efforts of many leading men, both at home and abroad. The recognised association betwixt irritable ulcers and gouty individuals at once suggested a suspicion of "suppressed gout". The treatment was directed accordingly, and in three weeks the ulcer was well.

Such are the consequences of having therapeutic measures directed by a diagnosis which does not merely recognise the characters of a disease, and register its physical signs, but which penetrates into the conditions upon which that disease causally depends. The one is a mere intellectual feat, chiefly involving the mnemonic mechanism; the other involves a deeper insight, and becomes of actual utility to the patient.

Our knowledge of the chronicity of some forms of renal disease, and of the light which pathology now affords us of the slow insidious changes which precede marked and unmistakable kidney-disease, tells us that such renal mischief may exist with tolerable and even good general health for many years, the defective renal action being helped out, or supplemented, by compensating activity in other organs; that intervals of apparently perfect health may intervene betwixt these explosive cleansing processes; and yet that the condition of the kidneys upon which these affections causally depend is persistent, irremovable, and even unchangeable, except for the worse. It does not follow that these compensating actions or consequential ailments shall always be present; there may be, and commonly enough are, long periods or intervals of comparative health. It only follows that the individual is liable to have such maladies at any time; much in the same way that a soldier is not always being wounded even in a campaign, though he is liable at any time to be wounded—and that, too, sorely, even unto death; or a seaman is not always battling with storms, though he is liable to experience one at any time, and each storm may endanger his existence.

We must not, however, run away with the idea that the consequences or outcomes of this renal inadequacy based on organic disease, and

ordinarily termed "suppressed gout"—a happy term conveying at once the idea of latency and of the true pathology of the condition—are alike in different individuals. Far from it! Though, to a certain extent, its sequences are interchangeable, its different manifestations are directed by various conditions. In some families the changes are almost confined to the vascular system: apoplexy threatening during the period of hypertrophy of the left ventricle, and cardiac failure ultimately ensuing after degeneration has undermined the muscular structure of the heart. In others of a nervous diathesis, the consequences of suppressed gout fall chiefly upon the nervous system, especially in the form of those neuralgic of advanced life, so well described by Anstie. In women, there is often gouty dysmenorrhœa. In others, the manifestations are those of gout proper, especially in the phalanges of the extremities. In some, again, the tendency is to form masses of connective tissue in the valves of the heart, in the joints, or in the viscera. In one case, which has come under my notice, there is a dense patch of connective tissue in the palm of the left hand: the gentleman, a retired member of the profession, is an amateur geologist, and rests in his left palm the specimen he chips with his hammer. In agricultural labourers we usually find a dry inactive skin, rheumatic pains, fibrous thickening of the sheaths of tendons, and affections of the joints: chronic rheumatism, in fact, is the form assumed by chronic Bright's disease in them.

The diathesis, the occupation, the presence or absence of exposure to the weather, have much to do with the systemic indications of the primary renal disease. The peasant labourer never has gout in his great toe, or very rarely, and yet the affection is very common in portly butlers, who are heavy men, and who lean much upon their toes when waiting at table; though, in each, it may be found in the hands. The person of nervous diathesis does not suffer so severely from the changes in the vascular system to which some are most liable: while these latter, again, are not commonly subject to gouty neuralgia. I have at present under care a lady, who has suffered much from gouty neuralgia, complaining of gouty intermittency and palpitation, in whom the vascular system is almost free from structural change. Unlike, however, as are the different forms assumed, the origin is the same in each: and it is the recognition of that causal origin which is so important in giving the correct and rightful direction to the curative or palliative measures.

It is impossible to allude to the treatment of chronic Bright's disease here.

It shows also that the vomiting was evidently a necessary effort of nature to eliminate the poison; and thirdly, it is remarkable that the child should have been affected *in utero* and desquamating when born.

D. M. WILLIAMS, L.K.Q.C.P.L., Physician to the
Liverpool Hospital for Consumption and Diseases of the Chest.

UNUNITED FRACTURE OF THE FOREARM, WITH DEFICIENCY OF THE ULNA, TREATED SUCCESSFULLY BY EXCISION AND THE WIRE SUTURE.

By THOMAS ANNANDALE, F.R.S.E.,

Surgeon to the Edinburgh Royal Infirmary and Lecturer on Clinical Surgery.

R. K., aged 29, was admitted into my wards on June 24th, 1873, suffering from an ununited fracture of the bones of the forearm. About six months before his admission, his forearm had been severely injured by machinery. Both bones were fractured, and a large lacerated wound was caused by the accident. He was taken to a provincial hospital, and carefully treated for several months. About three months after the accident, a large piece of bone (a portion of the ulna) gradually loosened, and was removed. Three weeks after this, the wound was healed, but the bones had not united properly.

When the arm was examined, a large cicatrix was noticed over the middle third of the bones of the forearm; it was adherent to the ulna for a short distance, but was otherwise free. Both bones were movable at the junction of their middle and lower thirds, but the radius less so than the ulna. The ulna was not only quite ununited, but was deficient for about one inch at the seat of fracture, the result, no doubt, of the necrosis which had followed the injury. The fractured ends of the ulna were displaced towards, and adherent to, the radius. Pronation and supination could not be performed, and the arm was also weak, and, in consequence, useless.

On June 27th, I performed the following operation, with the hope of making the arm more useful. An incision, about three inches long, was made over the dorsal aspect of the ulna, so as to expose the fractured portion of this bone. It was then found that the fractured ends were rounded off and atrophied, and united to one another and to the radius by some strong fibrous texture. These ends were also displaced inwards, and there was fully an interval of an inch between them owing to the deficiency of the bone.

The condition of the bones is illustrated diagrammatically in Fig. 1, the dotted lines at A A and B B showing the amount of bone removed from the radius and ulna at the operation.

2

a portion of this bone, including the partially united part, was also sawn off. By thus shortening the radius to a sufficient extent, the ends of the ulna were allowed to meet, the adhesions connecting them to the former bone having been divided. The ends of both bones were then drilled and secured with strong silver wire, as shown in Fig. 2. The edges of the wounds being brought together with a few carbolised silk sutures, antiseptic muslin was applied in the usual way, and the arm adjusted on a splint. On the 3rd of July, it is noted that the patient has progressed favourably since the operation, and the wound is healing well. On the 5th of July, the wire through the ends of the ulna being a little loose, was twisted more firmly. The patient's progress continues good.

On the 3rd of August, the wounds were quite superficial, and the wire through the ends of the radius being quite loose, was removed. On the 13th of August, the wire was removed from the ulna; and on the 29th, the patient left the hospital, the wounds being almost healed.

Six weeks after this, he returned to show himself, when it was found that the bones were firmly united. The forearm, to a limited extent, could be pronated and supinated; but these and the other movements of the arm were steadily improving, and the limb could already be used in many ways, its strength being greatly improved since the operation.

Remarks.—For the successful treatment of this case, it was necessary to overcome two principal obstacles. These were: (1) the deficiency of the ulna; (2) the displacement inwards of the ends of the ulna, and their adhesion to the radius. In addition, the large cicatrix forming the chief covering of soft parts over the injured bones made operative interference more difficult than if these coverings had been sound. The first of these obstacles was successfully overcome by removing a portion of the radius, so as to allow the ends of both bones to be brought together. The removal of this portion of bone by diminishing the amount of the osseous element of the forearm also permitted the contraction of the wounds in the soft parts to take place satisfactorily. The second obstacle was successfully combated by dividing the adhesions, drilling the ends of both bones, and securing them with strong wire, as shown in Fig. 2.

This method of securing the fractured ends would, I believe, prove very valuable in many cases of recent compound fracture of the bones of the forearm. It is a most efficient means of preventing their inward displacement, and therefore assists much in preventing also the union of the radius and ulna to one another, a condition not easy to overcome in this class of injury. The wire which I employ in this and other operations of the kind is silver, of the thickness of that usually employed to secure the corks of soda-water bottles. The instrument used for drilling the bone is a joiner's common small pricker. Having tried more complicated instruments for this purpose, I have now a decided preference for the more simple tool, which I always find to be most efficient.

MALARIA: REPLY TO DR. INMAN.

By W. C. MACLEAN, C.B., M.D., Surgeon-General,
Professor of Military Medicine in the Army Medical School at Netley.

ALTHOUGH I have no intention of entering into a controversy with every member of the profession who happens to believe there is no such entity as malaria, I must ask to be allowed space for a few words on the not very courteous article of Dr. Inman.

1. The candid confession with which his letter opens, that he has no personal experience of the subject on which he writes so confidently, was hardly necessary; the fact is sufficiently apparent in his letter.

2. I beg to say that I did not "attack" Dr. Oldham. This gentleman published a book, in which he put forth certain opinions, the accuracy and scientific value of which I have called in question: a very different thing from "attacking" their author.

3. When Dr. Inman, in effect, asserts that I have not read his friend's book, he is in error. Dr. Oldham was kind enough to send me a copy of his work when it issued from the press, when I not only read it with care, but, without loss of time, communicated to its author, as well as I could within the limits of a letter, the grounds on which I differed from his conclusions.

4. Dr. Inman has evidently no knowledge of what I have elsewhere written on malarious fevers, if he supposes that I am ignorant of the notorious fact that paroxysmal fevers are seen in some localities where there are no marshes, and in ships at sea. In the first instance, water is often found at no great distance from the surface, and the apparently barren soil has been found to abound in organic matter; to the above conditions add high temperature, and we have the factors needful for the genesis of the poison of malaria. In other cases, where such fevers have been found to prevail on rocky places with scanty or no

Fig. 1.

Fig. 2.

About a quarter of an inch was now sawn off the ends of the ulna; and, as it was quite evident that these ends could not be brought together, a second incision was made over the dorsal aspect of the radius, and

vegetation, it has often been found that the rock consists of granite in process of disintegration, in common language, "rotten granite", holding an immense amount of moisture, and largely charged, as Friedell has shown in the case of Hong-Kong, with fungi, which, with the addition of high temperature, give, when exposed to the air, the conditions required for the generation of malaria. In yet a third class of cases, it has again and again been found that the cause of the fever has been traced to the condition of the drinking water in wells left uncleansed for ages, and charged with malaria, the result of the decomposition of organic matter accumulated in them. In every known case of malarial fever occurring in ships at sea, the cause of which has been investigated by competent persons, it has been traced to one of three causes: (a) either recent charging of the systems of the victims with malaria, by residence in a malarious locality, as is seen every day in our invalids returning from India; or (b), the genesis of malaria in the holds of ships by the decomposition of vegetable matter, e.g., chips left by ship-builders, acted on by bilge-water and high temperature; or (c), a still more frequent cause, the issuing to the crews of drinking-water taken from places notoriously malarious, as in the famous example carefully recorded by Boudin. If chill after exertion could generate a genuine paroxysmal fever with its sequels, this class of fevers ought to prevail as a common disease among the maritime population of all countries, which is not the case.

5. Dr. Inman dismisses with a sneer the examples I gave in my critical notice of Dr. Munro's paper, of malarial fevers following immediately on disturbance of the soil in Hong-Kong and Paris. But the facts cannot be sneered away. It was not the workmen engaged in the above operations, heated by day and chilled by night, who alone suffered, but the population exposed to the emanations from the soil, as recorded by many observers quite as competent to note natural phenomena as either Drs. Oldham or Inman.

At Hong-Kong, at the time indicated by me, four officers of Artillery, of whom my friend Major-General Barrow, C.B., is now the sole survivor, occupied a bungalow at a considerable height above the level of the hill-side on which excavations for building were being carried on. They enjoyed perfect immunity from the fever which prevailed lower down. At last, a young and inexperienced officer insisted on scarping away part of the hill-side, to give more room in rear of his own bedroom, thus exposing a large slice of soil to the air. The result was an attack of remittent fever that cost him his life, with the dangerous illness of two of his brother officers from the same cause; and the immediate abandonment of the house was rendered doubly necessary from the prostration of most of the servants, who, up to this time, had escaped. Will a reference to the stale joke about "Tenterden steeple and the Goodwin Sands", explain such a fact as the above? There is not a coffee-planter in India who could not give Dr. Inman many such examples from his own experience.

6. Dr. Inman justly enough points to the fact that chills cause bronchitis and pneumonia, and, as in the case of the servant-girl mentioned by him, congestion of the kidneys, and he might have added, rheumatism in all its degrees. Who disputes so familiar a fact, known to every adult person in this realm? What Dr. Inman fails to see is that, when men die from any of the above causes, we do not see in their organs after death the changes observed with an uniformity as remarkable as the phenomena of the disease itself, in those who perish from malarial fevers—the diseased blood, the pigmented organs, the diseased spleens and livers, the tinted skins, in a word, the whole train of morbid appearances characteristic of the malarial cachexy. If Dr. Inman, instead of taking his notions on malarial diseases at second hand, will pay us a visit at Netley in the coming summer, it will give me pleasure (as much pleasure, at least, as can be derived from the contemplation of so sad a sight) to show him, by the hundred, men with the stamp of malaria on them so plainly marked that those who run may read; and on the shelves of the museum the results of the action of an agent, that, call it by what name we please, works on the organs of man, in a way not explicable by the "chill" theory of Dr. Oldham or his supporters.

THE TREATMENT OF ACUTE RHEUMATISM.*

By THOMAS S. DOWSE, M.D., F.R.C.P.Ed.; Medical Superintendent of the Central London Sick Asylum, Highgate.

As a mere humble clinical observer, I should not have ventured to trespass upon the valuable time of this Association, if I did not feel that, in the relief of suffering humanity, as far as our honest endeavours extend, we are each and all of us upon one common level. The

* Read before the Medical Section at the Annual Meeting of the British Medical Association at Norwich, August 1874.

end and aim of medical science is not to record an age of special originality, unless it have a direct bearing upon an improved treatment in the art of healing, and the simplest paths of learning in this respect must not be ignored. The rapid advances which have been made of late years to throw a flood of light upon a hitherto darkened spectrum, must claim at all times our warmest approbation and most careful scrutiny. Yet there are some, and by no means unessential, points in the treatment of diseased states which no aids at our command can reveal, save the practised eye and careful observation of the painstaking practitioner. In the few remarks which I am about to make to you, I shall not allude to any obscure theories, but I shall confine myself strictly to the practical part of my subject. The essential nature of my treatment of acute rheumatism is both eliminative and pyretic. I believe it is usually admitted that the *materies morbi* circulating throughout the entire body in this disease is of an acid character—lactic, if you will; and, although there might be some doubt as to whether this is correct or not, still it is quite certain that we have a condition to deal with in which acidity is the most prominent feature. I am not aware that its causation has been explained in any more definite way than that it is in all probability the product of malassimilation producing faulty tissue-metamorphosis. The vagueness of such a definition as this must at once be admitted. It is quite certain that especial individuals are prone under fixed laws to the generation of this rheumatic factor; that the like individuals are especially subject to a nervous condition known as chorea, and that these alternate in the same person is a matter of daily observation; but the relation which this has to the etiology of acute rheumatism, on the one hand, and chorea, on the other, has never to my mind been explained.

It is the rule (not, however, without its exceptions) that the poison of rheumatic fever is generated in an especial type of constitution, and characterised by a definite train of symptoms and signs which are well known, and need not be here enumerated. In addition to these, however, we have fibro-serous inflammations and muco-congestive complications.

It would be useless for me, in the short space of time allotted to the reading of this paper, to attempt to describe fully the various opinions which have from time to time been put forward in reference to the treatment of this disease; but, under all circumstances, the chief point of clinical interest to the physician must be to prevent inflammation of the heart and its membranes. For some time, the alkaline treatment so much advocated by the late Dr. Fuller held unbounded sway, and the admirable tables drawn up by Dr. Dickinson in 1869 prove most incontestably that alkalis have the power to prevent endocardial and pericardial inflammation. In this year, Sir William Gull and Dr. Sutton somewhat startled the profession by bringing forward a number of cases successfully treated by mint-water; in other words, by adopting careful regimen, mechanical and physiological rest, and allaying pain by opiates. Under this treatment, the average duration of the acute symptoms was seventeen days. Some years ago, when I was registrar at Charing Cross Hospital, the treatment of this disease occupied my serious attention. Dr. Salter gave three grains of quinine every three hours, whilst Dr. Headland gave alkalis. I then found that the course of the disease was cut short by the quinine, but that the tendency to heart-complication was greater than when it was treated by alkalis. From a careful survey of the various modes adopted in the treatment of acute rheumatism, including vapour-baths, lemon-juice, tincture of iron, aconite, hydrochlorate of trimethylamin, blistering, and others, I am inclined to think that its progress can be cut short by the means which I shall immediately explain to you, and that cardiac inflammations can be avoided. I am right in stating it to be an admitted rule that, if valvular disease of the heart or pericarditis supervene upon an attack of rheumatic fever, it does so within the first week or ten days. This is to a certain extent undoubtedly correct. I am one of the few who believe that inflammation of the endocardium is a constant attendant of the acute rheumatic state, not giving rise in many cases to valvular lesion at the time, but predisposing to subsequent change, which reveals itself under circumstances apparently the least provocative. It is quite true that in acute rheumatism no absolute *bruit* referred to the sounds of the heart can, in the majority of instances, be detected, and at the base the sounds will be clear and natural in rhythm, but at the apex they will be attended by a characteristic turbulence and commingling, which, with the hurried action of the heart and feeling of oppression in the epigastrium, will be indicative of hyperemia of the mitral valves.

Thus it seems to me that, in the treatment of rheumatic fever, we have, first, to consider the best way to eliminate the acid products of the diseased state; secondly, to relieve pain. Beyond this, the case can be treated as an ordinary one of functional glandular derangement, or febricula; for, when once the sour secretion from the skin is

eliminated (no matter how acid the urine might be), the pain subdued, and the temperature influenced, we need have no fear of heart-complication arising. Then comes the question, What are the best means, if there be any, to bring about this condition?

During the past three years, I have been in the habit of packing most of my cases in a wet blanket, and afterwards rolling them up in dry blankets, so as not only to promote profuse sweating, but also to increase the temperature. This mode of procedure, which I conducted in a very indefinite manner, gave such good results, that I thought carefully over the *rationalité* of the system, and at once adopted a course of wet packing after the manner and with the success which I will relate to you. The procedure is simple. The bed is covered with India-rubber sheeting; over this is laid a blanket which has been wrung out of hot water. The patient is then enveloped in the blanket, and covered with six folds of dry blanketing. By this, the temperature is raised and profuse sweating results: the former, if need be, is assisted by the administration of brandy in half-ounce or ounce doses every hour, and the latter by giving freely warm milk and water. If the temperature exceed 102 deg., then the stimulant is unnecessary. My plan is to continue the treatment for three successive days; namely, for six hours the first day, four the second, and two the third. After the first pack, the patient is free, or nearly so, from pain; after the second pack, the pain has completely subsided, and after the third pack the sour smell usually disappears. In addition to the relief from pain and subsidence of acid secretions, the pyrexial state, with its attendant symptoms, will be found to decrease in direct ratio, and likewise the pulse. The secretion of urine will become more plentiful and the urea will diminish in quantity; yet, although the improvement is so marked in reference to pain, sweat, pulse, and temperature, the urine remains acid and loaded with lithates, and the tongue coated, for some days longer. It not unfrequently happens, especially in young people, when the weather is variable, that transitory pains return in one or more joints; but in almost every instance the pain has been subdued, if not by the first, by the second bath. In reference to cardiac inflammation, I believe that this treatment subdues it more rapidly than any other, rendering the valves less likely to undergo organic change.

But now comes a very important practical question. There can be no doubt that the packing process produces considerable constitutional disturbance. Under what circumstances should this treatment be adopted, and under what conditions is it not practicable? Every one who has had much to do with this disease must be conscious of the anxiety which it gives him when the temperature exceeds 105 deg. or 106 deg., and especially when it is associated with the least sign of cerebral disturbance; and, as my treatment consists in elevating the temperature, it will be apparent that some care is necessary. Thus, according to my experience, it should not be adopted—1. If the patient suffer from incompetency of the aortic valves; 2. If there be much fluid in the pericardium from previous inflammation; 3. If the temperature be over 104 deg.; 4. If the skin be hot, dry, and harsh, without the least tendency to sweating; 5. If there be extreme nervous prostration from habits of drunkenness or other vitiating cause; 6. If the patient be pregnant.

Again: during the time the patient is packed, the following points must be observed:—1. If, after two or three hours, the patient become very restless, with a dry non-perspirable skin, I should advise the treatment to be discontinued; also when the temperature exceeds 105 deg.; 2. If the temperature do not rise, and the patient be sweating freely, give half an ounce, or even an ounce, of brandy every hour in warm milk and water. Thus we have to secure profuse sweating and a mean temperature of 104 deg.; we have to guard against a dry skin and a temperature over 105 deg.

Let us consider this a little more practically. If a healthy child be packed for six hours, as directed, whose normal temperature is 99 deg., we find that it will only rise one degree during the whole course of the six hours, and the administration of stimulant will not cause it to rise any more. It is very different when the pyrexial stage of acute rheumatism, and I have proved most markedly so, when the packing alone does not increase the temperature, this is easily brought about by giving brandy in the manner just stated. I have adopted this treatment with excellent results in cases where there has been, in addition to the rheumatic inflammation, a mitral murmur, pericarditis, and pleuropneumonia. In some cases, I give medicine, in others I do not. My rule is this: not to give medicine or solid food until after the third packing, and this means not until the acute symptoms have subsided and the temperature is down to 100 deg.; then some vegetable tonic, with solution of acetate of ammonia, is to be preferred to large doses of alkali or quinine. If, however, the case have been of long duration before coming under treatment, and if it be the third or fourth attack, with probably cardiac disease, then of course the orthodox measures must be resorted to for such complications. If the temperature should

run very high, with tendency to delirium, I believe the best plan is in every instance, whether under the packing treatment or otherwise, to apply ice to the head, expose the body freely to a current of cold air, and sponge it over lightly with a mixture of one part of spirit to two of water, until the temperature falls; then to discontinue this, and to apply a sinapism to the epigastrium. The following case occurred in my practice, from which a lesson might, perhaps, be learned. A young robust woman, aged 19, came under my care with incipient acute rheumatism, but with a dry harsh skin and a temperature of 102 deg. I had her packed in the usual manner at 1.30 P.M.; at 4.30 P.M., there was no action of the skin; temperature, 104 deg.; at 6.30 P.M., still no action of the skin; temperature 106.2 deg.; rapid action of the heart and tendency to delirium. I at once applied ice to the head, bathed the exposed body with spirit and water, and in twenty minutes I was pleased to find the temperature down to 103 deg.; the following morning it was 101 deg. Again: a woman, aged 28, of drunken and dissolute habits, came under my care with the third attack of acute rheumatism; there was considerable prostration and a temperature of 103.2 deg. I thought that I detected a fine murmur obscuring the second sound at the base of the heart. I ordered her to be packed in the usual way; but her temperature continued to increase, until it reached 110 deg., and she died. This is the only case which has terminated unfavourably out of a very large number. Whether the high temperature arose from the treatment, I am unable to say, and, as such cases do occur now and again under any treatment, I must decline to give an opinion.

(*From Brit. Med. Journal*)

ON DIPHTHERIA.*

By THOMAS PRANGLEY, M.R.C.S.Eng., Aylsham.

OUR acquaintance with diphtheria being of so recent a date as to render it doubtful whether we have as yet witnessed all its phases, is the excuse for bringing before you such facts and information as I was enabled to gather from notes of fifty-six cases which came under my notice during an outbreak which occurred in my neighbourhood in the summer and autumn of 1868. As it is impossible in a paper of this kind to treat the subject in an exhaustive manner, I think I shall be best employing the time in discussing those points which may guide us in our prognosis and treatment; and shall make reference only to the cases which have fallen under my own observation, without availing myself of the labours of others.

During the epidemic which I witnessed, the disease assumed all degrees of severity: thus sometimes it so little affected the health, that the patient could remain at work, and would recover in a few days. In the majority of cases, however, the disease as a rule ran a much more severe course; in some cases coming on so insidiously, that the patient was in the jaws of death before I saw him—killing not through any local complication, but by general poisoning of the system, characterised by the predominance of asthenic symptoms and the exhaustion of the vital powers. Other cases were characterised by symptoms of apnoea, caused by the extension of the membrane to the nares, larynx, and trachea.

The actual "soreness" of the throat afforded no indication of the severity of the attack; for, though there was generally considerable pain during deglutition, in some cases it was so slight as to be scarcely appreciable. Thus I have notes of two cases of unusual severity, in which there was absolute immunity from pain on swallowing. In one of these, the throat was covered with a large grey membrane, and in the other case, that of a child, who ultimately died, both tonsils were covered with grey slough, and the lower part of the uvula sloughed; but there was no difficulty in swallowing. As a rule, it was more severe with children and in those cases which were ushered in with acute febrile symptoms, and was generally most experienced during the period of the membrane disappearing; so that I began to look upon the statement "that the medicine cut the throat" as a good sign; and the absence of all pain nearly always revealed on inspection a thick mass of grey slough, and was consequently a bad sign.

The variety of forms which the false membrane assumes, and the various conditions of the tonsils, are very remarkable; thus I have seen the membrane in consistence like glazed starch, cream, wet parchment, and a greyish flesh-like pulp of all degrees of colour, from the purest white to almost black. I have seen it in specks, patches, shreds, and in large firm membranes, forming an exact cast of the part it enveloped. I have seen the specks or patches surrounded by a bright red border,

* Read before the Medical Section at the Annual Meeting of the British Medical Association in Norwich, August 1874.

or gradually becoming thinner at the edges, imperceptibly losing itself, so that one could not exactly say how far it extended. I have seen the tonsils engorged to such an extent as to almost meet, or enlarged laterally, as if they had been flattened by a weight on their surfaces; and I have notes of one case in which the tonsils were rather depressed. The glands at the angle of the jaws were more or less enlarged; but I never saw them suppurate. In arranging my notes of various cases, I find that in some the membrane was confined to one tonsil throughout—but these cases were rare; in others, it affected both tonsils; in others, the uvula was also affected, and in two cases sloughed off. In several, the membrane covered the palate and pharynx, and, in the most severe cases, spread into the nares and trachea.

The practical question is, Will these appearances in the throat guide us in the formation of a correct prognosis? I think this may be answered in the affirmative; for, if we do not find the tonsils engorged, or only enlarged laterally as if flattened, and if we find them covered only with specks or patches, and more especially if these be defined by a surrounding bright red border, and if the glands at the angles of the jaws be not much enlarged, we may foretell a favourable issue. If, on the other hand, we find the tonsils prominent, the fauces red or dusky, and if we find them covered with a glairy fluid like starch, or the patches undefined, so that we cannot satisfy ourselves where they terminate, we may be almost certain that the next time we examine we shall find the starch converted or the patches coalesced into one mass of thick membrane, and shall be more cautious in our opinion, and congratulate ourselves if our fears of a severe case be not realised.

The manner in which the membrane disappeared and the throat recovered varied considerably. In some cases, it broke up into shreds, and was either swallowed or expectorated with mucus; in other cases, it exfoliated entire, and in these, similarly to what happens if it be artificially removed with the forceps, a new membrane appeared, but of less density than the one which preceded it. Thus I have seen as many as half-a-dozen successive membranes form one after the other, each one of less density than its predecessor, till at last a thin film of almost transparent lymph was the last trace of exudation. In other cases, the membrane retained its original form to the last, and seemed to imperceptibly waste day by day, becoming gradually thinner and more transparent; so that I frequently find such notes as these in my case-book: "Membrane seems to be gradually getting thinner"; "Membrane has gone apparently by absorption."

On a few occasions, after the entire disappearance of the membrane, I found the tonsils again speckled all over with small white cheesy spots. These need cause no alarm; for, though they remained *in statu quo* for some days, they always disappeared without further inconvenience.

One of the worst signs in this disease was the extension of the membrane to the nares, so that I looked suspiciously upon the unfortunate patient, who began to use the pocket-handkerchief too freely. This invasion of the nares was manifested by redness of the margin of the nostrils and a discharge of thin mucus, which rapidly became purulent and, as the disease progressed, very abundant; so that the sole occupation of the patient seemed to be wiping the nose. I possess notes of four cases in which this complication was very marked, and in neither was it delayed later than the sixth day. The constant discharge, acting as an irritant, soon produced excoriation of the edges of the nostril and upper lip; and, in one severe case, these parts were covered with scabs, bleeding at the least touch. The spread to the nares may be apprehended when we find the membrane rapidly spreading over the soft palate; and, in all the cases I have seen, it appears to have reached the nares by this route, and not from an independent centre. In one case, the left nostril was blocked up with membrane, which was one day suddenly discharged, forming a complete cast of the nostril, and at once set the passage at liberty. While this nostril was blocked up, a very curious phenomenon occurred, showing at all events that the nasal duct was patent; whenever the patient swallowed fluids, some would come down the nose, and some would appear at the corner of the eye, making it smart. Of the cases in which the nasal complication was present, three died.

The propagation of diphtheritic membrane to the larynx and trachea is another ominous symptom. I have notes of seven cases—all children—in which this occurred, and of these four died. In some cases, it is the only dangerous complication, and may kill by asphyxiating the patient by suffocative paroxysms; and in others it is an additional burden to the unfortunate who has the disease already established in the nares. Its presence is usually first announced by a small dry cough of a peculiar character, resembling that of croup; then the voice becomes affected, and shortly the breathing becomes difficult, each inspiration producing a kind of whistling sound. As the disease progresses, the voice

becomes more and more hoarse, till at last it is completely muffled, and the patient speaks in a whisper.

A peculiar feature which I have observed in these cases is an intermittence in the symptoms, which at first induced me to give a too favourable opinion, and to congratulate myself upon the efficacy of my treatment; thus I have seen the fits of dyspnoea reduced in frequency, the respiration becoming more regular, and an almost entire remission of laryngeal whistling; and then, at shorter and shorter intervals, especially at night, all would recur, the patient, apparently without any exciting cause, starting up in bed, making immense efforts to breathe, and, after a severe suffocative fit, falling back on the bed, blue in the face and exhausted. These fits may recur over and over again for some hours, and then another remission occurs, most probably only to be succeeded by a more severe exacerbation, till at last, after one severe effort, the agonies of death close the scene.

It may be well to pause here a moment to consider what is the cause of these intermissions, which so cruelly raise false hopes in the patient and his friends. Is it the displacement of a portion of the membrane in the trachea, being either coughed up, or, valve-like in its action, being pressed close to the walls by the force of inspiration, and thus permitting the free ingress of air? or does it resemble one of those pathological phenomena which we meet with, but cannot explain, in such diseases as cancer, where the pain is intermittent? or does it, as in asthma, depend upon the additional element of spasm being added to the burdens? I think that the latter explanation is the most probable; for the suddenness of the attack, and its more frequent recurrence in the night, seem to favour this view.

In connection with this, I will call your attention to a phenomenon which frequently occurs in this disease, and that is "noisy breathing" during sleep. This is to be distinguished from laryngeal breathing, or we may unnecessarily alarm ourselves and patients. There is no stridor, no affection of the voice, and no suffocative paroxysms. It appears to me to arise from mere obstruction in the throat, and is still worse if the nares be implicated.

Time will only permit me to simply mention without comment certain sequelae. Of these, I have observed marked anaemia, dyspeptic symptoms, tendency to faintings, and various symptoms depending upon loss of nervous force, such as aphonia, paralysis of the palate, protracted difficulty in swallowing from paralysis of the pharynx, defective vision, depending upon loss of power in accommodation, such as presbyopia and diplopia, wry neck, and various degrees of general paralysis, from numbness and tingling of the hands and feet to total paralysis, preventing the patient from moving in any degree. Of these affections, paralysis of the soft palate and defective vision were the most frequent.

Passing over many interesting points in the clinical history of this disease, I proceed to the practical question of its treatment, which resolves itself into—local, directed to the throat itself; general, to combat with the great tendency to depression of the vital powers; and individual means to relieve certain symptoms which may arise during its course.

The local treatment I adopted in every case was the application of tincture of iodine (forty-eight grains to one ounce) to every part of the throat covered with membrane at least once in twenty-four hours, and the inhalation of iodine vapour mixed with steam, but more especially the latter, if the larynx were invaded. If the membrane were firm in texture, and not too strongly adherent, I always removed it and applied the tincture of iodine to the denuded surface, and with the best results; for, although frequently the membrane would re-form, yet it never regained its pristine condition. If the membrane were in specks or shreds, I applied the iodine over them, and in general half-a-dozen applications were all that was required to procure their dismissal, and in several instances two applications were sufficient. This local application of iodine acts, not only as a caustic, but, I believe, confers a modifying influence upon the secreting structure, and further brings into action the power of the absorbents; thus tending to retard the spread of the membrane and to promote the removal of that which is formed. I am aware that, in urging this treatment, I am at issue with many who contend that, in this disease being a general one depending upon certain changes in the blood by the introduction of a specific disease-poison, it is useless to attack the local manifestation of the disease any more than the pustules of small-pox. To those I would call attention to John Hunter's axiom, that two similar diseases cannot coexist in the system at the same time. For example, he states that, if you can succeed in changing the nature of an inflammation, you can often cure the original complaint. Higginbottom's method of arresting the spread of erysipelas by vesication with nitrate of silver is a familiar illustration of this Hunterian law; and, if that treatment be effectual in erysipelas, why should not a

similar treatment be equally efficacious in diphtheria? Again, I believe that the local manifestation of blood-poison is of itself a great indication for treatment; for do not all poisons have some definite and specific action on some membrane or organ? Thus does not arsenic exert its influence chiefly on the mucous membrane of the stomach, colchicum on the ligaments, cantharides on the kidneys, and strychnine on the spinal cord? Then why should not the throat be the chief seat of the diphtheritic poison, and, if so, why should not the rational treatment be to arrest and destroy it at its first encampment? Again, if my experience be correct, that one of the most formidable symptoms we meet with is the extension of the membrane to the nares and trachea, and, with my opinion be correct, that it does not arise there by an independent centre, but by extension of the membrane from the fauces,—is not this an additional reason for staying the progress of the membrane and limiting it to the fauces, whether we adopt caustics or any other means with that object in view? That iodine possesses this property, I feel convinced; and, as I am not reading to you a treatise on diphtheria, but simply my own experience, I shall not enter into the merits or demerits of the various remedies which have been vaunted by numerous successive writers. The efficacy of any treatment is proved by its results; and, as I have stated, out of fifty-six cases which I have noted, seven died, of which five were moribund when seen, and only two died fairly after treatment.

The general treatment was supporting and stimulating throughout. A liberal supply of beef-tea, wine, and milk was frequently and regularly given, to maintain the system against the natural tendency to depression and exhaustion. In medicine, I rely upon chlorate of potash and tincture of steel, from three to five grains of the former with five to fifteen minims of the latter every four hours, according to age. When tracheal symptoms arise, I at once have recourse to the inhaler, beginning with ten drops, increasing to a drachm of the common tincture of iodine to a pint of boiling water, and letting the patient inhale as frequently as possible. In using this, one precaution is necessary, and that is not to begin with too large a supply of iodine, otherwise it is too irritating, causing the patient to cough, and making him unwilling to use it. I have found ten drops well borne to begin with; and, after a short time, we may gradually increase the quantity to a drachm to the pint without inconvenience. If this do good, which it undoubtedly does, it is evident it cannot be by any caustic action, but entirely through its modifying and absorbing influence upon the diseased tissue. I can refer to three cases in which this treatment was of marked utility. In cases where the fits of dyspnoea are severe and frequent, I have found nothing like an emetic of sulphate of copper, which generally expels a quantity of membrane from the larynx and trachea, and gives relief for a time at all events.

In tracheotomy I believe we may place considerable reliance, although my experience is limited to one case, and that unfortunately a fatal one; yet I firmly believe that, if it be resorted to soon enough, we may rescue many lives. There is no doubt one feels inclined to put it off as long as possible; for parents have a curious repugnance to having their children's throats cut; and, if you are not successful, they speculate upon what assistance you afforded nature in her process of dissolution, and generally the balance is against the doctor; yet the evidence of numerous published cases, of which, roughly speaking, one-fourth were successful, proves that it is our duty not to neglect this chance of saving life, and more especially not to delay too long in resorting to it.

The treatment of the numerous sequelæ is difficult to formulate. I believe time and the *vis medicatrix nature* to be our most important agents; yet something can and ought to be done, for it would indeed be cruel to leave a poor patient totally paralysed without the hope of some assistance to the slow progress of nature. In those cases, I generally prescribe the liquor strychnine in five minim doses, gradually increased to twelve, three times a day; but I candidly confess I think it often did no good, for I well remember one case in which I gave it for a whole month, the paralysis steadily increasing the whole time. I then left it off, and prescribed a liniment as a *placebo*, when gradual improvement commenced, and recovery ultimately took place; but, on other occasions, I have found it decidedly of service, though I am doubtful whether it be more active than quinine, mineral acids, and other tonics. I believe we must show our discretion by changing our tonics, till we find the one best suited to the individual case, than by habitually using one formula indiscriminately. In addition to the tonic regimen, I recommend, when practicable, a judicious change of air and scene. On one occasion, I had recourse to galvanism, with no satisfactory result. I believe that rubbing and shampooing the limbs is of some service; at all events, it does no harm; and the simultaneous use of a little embrocation no doubt assists the charm. Some of the dyspeptic symptoms I found very troublesome to treat. As a rule, bismuth gave the most

relief, combined with bland nourishment; and, when the acute symptoms had subsided, a combination of quinine and strychnine was of marked benefit in giving tone to the digestive organs.

For the tendency to faintings which sometimes occurs, I have given a dose of ether; but what is most important is to enjoin the recumbent posture till convalescence is well established, and even then I recommend a little wine to be taken before any exertion is used.

Having alluded to the general treatment of diphtheria and its sequelæ, there yet remains to be mentioned other minor points, which are of considerable importance to the suffering individual, by which we may alleviate suffering and hasten recovery. For example, where the patient complains of sore-throat *ab initio*, I have found an iron gargle (two drachms of the tincture to half a pint of water) beneficial; but this I have found too cutting when the membrane has disappeared, and then I have substituted one of borax and glycerine (two drachms of the former and one ounce of the latter to half a pint of water); and this gargle I have also found very useful to relieve the sensation of bread-crumbs and tickling in the throat, of which complaints are frequently made during convalescence. Where the denuded surface has proved to be ulcerated, a few touches of nitrate of silver assist the process of repair; and in one case where the tongue and roof of the mouth was so sore, that everything that was taken gave pain, I found that great relief was experienced by applying dry trisnitrate of bismuth powder with a camel's hair pencil just before taking food. In paralysis of the soft palate and regurgitation of fluids through the nostril, holding the nose during deglutition will be found very much to assist the act: this a patient of mine found out for himself, and I subsequently confirmed his statement in other cases. In these cases, too, I always advise thick drinks, which are more easily swallowed. When the pharynx is also affected, a large bolus is much more easily passed down than a small one, so that I have advised the collection of all the food in the mouth into one mass before swallowing. This is no doubt accounted for by the weakened muscular fibres of the pharynx being enabled to grasp a large bolus with less contractile effort, than would be required for a small one. In one case, I kept a patient alive for some days by giving the yolk of egg unbroken, and letting it glide down his throat, as it were. These are a few practical hints, which, from what I have seen, I believe to be useful; but the ingenuity of the practitioner will often be put to the test in coping with the anomalous symptoms which sometimes arise during the progress of this horrible, though interesting disease. Much might be written upon this important subject; in fact, a single case will often afford, in its chequered course, abundant matter for a long paper; but I have endeavoured to be as brief as possible, and, with that object in view, have entirely excluded the histories of cases which I should otherwise have liked to introduce.

A CASE OF TUMOUR OF THE BRAIN, SIMULATING APOPLEXY.

By ALFRED H. MARTIN, M.B.T.C.D.,

Assistant Medical Superintendent, Joint Counties' Asylum, Carmarthen.

M. L. was removed from Briton Ferry to this asylum in March 1868; and, from that period up to June 15th, 1874, had been under care and treatment in this institution. The assigned cause for her insanity was intemperance, and her aberration of intellect manifested itself by great irritability of temper, flying into ungovernable fits of passion without adequate provocation. The following extract from the case-book will show that the above history has been completely borne out.

"December 1873. Continues in fair bodily health and condition. Is employed regularly in the laundry, where she works steadily. Her mental state is much enfeebled; she is, however, coherent in her conversation, and replies to questions correctly. Is generally contented, and cheerful in manner and appearance; but, if thwarted in any way, becomes very much excited, loquacious, and abusive. Her desire for stimulants still exists, but is scarcely so prominent as formerly. Is always neat and clean in her personal appearance."

Since the above report was made, she had, in no material way, changed, up to the day of her death. She was occasionally troubled with slight attacks of dyspepsia, which yielded readily to appropriate remedies. She never made any special complaint of headache; there was no paralysis, either facial or in the extremities, and the pupils were perfectly equal and sensitive. Her sight, hearing, and other senses, were perfect.

On the evening of June 14th, she complained of not feeling well, and, for the first time, of pain in her head. She appeared slightly excited,

and when accused of having taken the other patients' beer at dinner, became noisy and abusive. Her pulse at the time was 76, full and strong. She was reported next morning as having been sleepless during the night, and occasionally noisy, quarrelling with another patient in the same dormitory; but, at 6 o'clock A.M., she got up as usual, and proceeded to her work in the laundry. She was noticed by an attendant to stagger about, and as she still complained of not feeling well, was taken back to bed. A short time afterwards, as she had fallen into a state of perfect unconsciousness, the medical officers were summoned; she was found by them lying on her back, breathing quietly; pulse 64, full but irregular, both in force and frequency; temperature slightly below normal. The complexion had changed, and was assuming the cadaveric hue. The right pupil was widely dilated, and quite insensible to the stimulus of light; the left pupil was naturally dilated and sensitive. The right side of the face appeared to lack expression, and the right corner of the mouth was drawn to the left. Her left upper extremity was flexed, rigid and immovable—the inferior one was also in the same condition, but to a less extent; slight reflex movements being produced by tickling the sole of the foot. She was perfectly unconscious, and could not be roused. There was no stertor. A brisk stimulating enema was administered, which brought away a copious evacuation, but without producing any favourable change in the patient's condition; and, the vital powers gradually failing, she died at one o'clock P.M.

POST-MORTEM EXAMINATION.—Forty-nine hours after death, rigor mortis was well marked. There were hypostatic stains on back and buttocks. The body was very fat and muscular; there was at least an inch of subcutaneous adipose tissue over the abdomen. The ribs were extremely thin and frangible. The anterior portion of the lungs was spotted with black pigment (due, no doubt to the fact, that for some years she had been the attendant on the laundry fires, inhaling of necessity small particles of coal-dust. The heart weighed 9½ ounces. A small quantity of fluid blood was found in the right auricle and ventricle, there were no clots in either side of the heart. The right auriculo-ventricular opening was 1¾ inches in diameter; the left, 1½ inches; the opening of the pulmonary artery, ¾ of an inch; the aortic opening, 1 inch. The valves were healthy and competent. The muscular substance was much softened. The right lung weighed 19 ounces; it was adherent at the apex to the costal pleura, and was congested inferiorly and posteriorly. The bronchi were filled with frothy mucus. The left lung weighed 14 ounces, and was in exactly the same state as the right one. The liver weighed 49 ounces. The gall-bladder was full. The peritoneal covering was adherent, tearing the substance of the liver when removed. The organ was passively congested; its substance was softened. The right kidney weighed four ounces; the left, three ounces. In both, several cones were shrunken, and partially obliterated. The substance was firm. The spleen weighed four ounces, and was slightly congested. The calvarium was increased in density. The encephalic mass weighed 47 ounces. The membranes were congested; the convolutions were flattened on the right side. The right hemisphere was in a state of white ramollissement. The right optic thalamus was smaller than the left. The central ganglia were softened throughout. In the right cerebral hemisphere, and forming the roof and part of outer wall of the right lateral ventricle, was a fibrous tumour, situated a little posterior to, but evidently pressing upon, the optic thalamus of that side. The choroid plexus was adherent to the tumour, which had no other attachments. In size, the tumour was about as large as a hen's egg, and weighed 2¼ ounces.

REMARKS.—Owing to the comparative rarity of tumour of the brain, I feel justified in publishing the above case. There are several points of interest to be noticed.

1. The fact of such a large tumour, and corresponding large amount of brain-substance in a thoroughly disorganised condition, having existed, without symptoms or physical signs, until within a few hours before death.

2. The sudden loss of consciousness, with the rapid development of all the physical signs of intracranial pressure in the locality of the right lateral ventricle.

3. The exhibition of irritable temper with mild mental confusion—mental symptoms to which Russell Reynolds has called attention as being symptomatic of cerebral tumour. But it would have been too bold in this case to predicate the existence of a cerebral tumour without other data on which to found a diagnosis.

History points out to the practical physician the utter impossibility of always being able to pronounce with certainty the exact nature of the lesion which exists in such cases.

CLINICAL MEMORANDA.

THE PATHOLOGY AND TREATMENT OF CHOLERA.

DURING the discussion which followed the reading of Mr. Hall's paper on the above subject at a recent meeting of the Royal Medical and Chirurgical Society, it was pointed out by Dr. Althaus that the theory advanced by that gentleman was not new, but had already been proposed by Eulenberg. Mr. Hall, in his letter in your issue of the 7th of November, still, however, claims the priority, stating that he is not aware that anyone had brought forward this theory previously to himself in 1869. I would call Mr. Hall's attention, and that of the profession in England, to a remarkable paper, in which his views were in every essential point anticipated by a countryman of our own, Dr. C. W. Bell, Physician to the Persian embassy, which was published in the *Medical Times* of the 11th March, 1848, and quoted in full in Braithwaite's *Retrospect of Medicine* of corresponding date.

Like Mr. Hall's, the starting-point of Dr. Bell's theory was that the cholera-poison acts as a powerful stimulant to the sympathetic system, and that the collapse of cholera consists essentially in general arterial spasm; and he works out the details of the theory with great ingenuity, very much in the same manner as Mr. Hall now does. This paper was too much in advance of the pathology of the day to receive the attention it deserved, and it seems to have passed entirely from the recollection of those who took part in the debate. Mr. Hall's ignorance with regard to its existence is more remarkable, because it has been more than once pointedly referred to in the *Indian Medical Gazette* during the last two years; and the students of my clinical class are familiar with Dr. Bell's theory, as one of the most ingenious that have ever been proposed in explanation of the symptoms and *post mortem* appearances of cholera.

It is generally admitted in India, that remedies, to be of any avail in the collapse of cholera, must be administered hypodermically; but the subcutaneous injection of chloral, according to Mr. Hall's plan, has not met with the success in Calcutta that the published cases led us to expect. I have myself treated only nine cases in this way, with but three recoveries, one of them being a mild example of the disease, which would probably have got well under any ordinary treatment. The experience of the gentlemen in charge of the General Hospital has been larger, but scarcely more encouraging; and I am informed that, since this plan of treatment was adopted, the cases have exhibited a somewhat higher rate of mortality than usual. In my own cases, I have noticed a rise of temperature after the injection of chloral in most instances, even when the cases were terminating fatally; but, beyond this and mitigation of the cramps, the distressing symptoms did not appear to be influenced by the drug in any marked degree. Cases of cholera dying in the *stage of collapse* have, not infrequently, an axillary temperature of 101 deg., or even 103 deg. Fahr. for some hours before death—a rise which often continues during the next two hours till a self-registering thermometer placed in the rectum may be found standing at 108 deg.; and I have learned to regard a rapid rise of temperature to a point above normal, with persistence of the restlessness, pullessness, and laboured breathing, as occurred in several of my cases treated by chloral, as of particularly evil import.

A. CROMBIE, M.D., Officiating Professor of Materia Medica and Clinical Medicine, Medical College, Calcutta; and *ex officio* Second Physician College Hospital.

CASE OF MUSHROOM-POISONING.

I FORWARD the following case as adding another to the list of poisonings by mushrooms. The patient was a clergyman, who had for two months been a curate in one of the large manufacturing towns of Lancashire. On Monday night, September 7th, he, in company with one of his sisters, partook of a large plate of mushrooms for supper, of which he ate the larger share; for some time before this he had not been in good health, and was evidently below par, as is well shown by the following fact. He had suffered much from toothache, and went to a dentist to have the tooth extracted, but was advised not to have it out, as the pain came more from debility of system than from the tooth. No immediate symptoms followed—i.e., he had no vomiting, pain, or purging; but for the next two or three days he felt very unwell and weak. On the Friday, he was so bad that Mr. Shepherd of Wigan was sent for, who prescribed for him, and said he would see him the next day. On the morning of the next day, he got up; but felt so ill that he was obliged to take to his bed, when he became rapidly worse, his chief symptoms at this time being dyspnoea, cerebral excitement, with fever, coupled with a rash similar to that seen in some people after

having eaten shell-fish. Dr. Crompton of Manchester was then telegraphed for, and saw the patient together with Mr. Shepherd and myself. On examining the patient, nothing abnormal could be found either in the thorax or abdomen to give rise to these symptoms; and Dr. Crompton was of opinion that they were due to contraction of the smaller arteries, caused by some poison circulating in the blood. He accordingly suggested that belladonna should be given, with the view of relaxing their tension; but, unfortunately, after two or three doses, it produced such violent delirium, with dilated pupils, that it was obliged to be discontinued, and a dose of chloral given to subdue the excitement. Bromide of potassium was then tried, at my suggestion, for some days, but produced no positive results. So, from that time, the treatment consisted in keeping up the patient's strength, and in aiding as far as possible the eliminating processes; and so it was tried to keep the patient alive until the poison had exhausted itself; but, unfortunately, he grew more and more feeble, was very apt to be delirious, and procured but little sleep. The pulse grew weak and frequent; the tongue brown, dry, and tremulous; the abdomen tympanitic; and in exactly a fortnight after the severer symptoms set in, he sank exhausted by the virulence of the attack.

It was most unfortunate in this case that the patient was so susceptible to belladonna, as it might have proved practically the value of atropine as an antitoxin to muscarin, the alkaloid contained in mushrooms. It shows, however, how virulently the poison will act when introduced into a system susceptible to its influence, or debilitated from any cause, while others may escape unscathed, as in the case of the sister, who ate from the same dish at the same time, but had no unpleasant symptom. This being the case, I think physicians should be careful in ordering mushrooms as an article of diet; and, at the same time, I think the profession should exert itself to try to find out what it is that sometimes converts a favourite and common aliment into a deadly poison.

CHARLES F. HUTCHINSON, M.D., M.R.C.S., Scarborough.

INFLUENCE OF VACCINATION ON THE FŒTUS IN UTERO.

WHEN I had charge of the Birmingham Small pox Hospital, I practised vaccination in several instances upon women at various stages of pregnancy. I have not had a single case of unsuccessful vaccination amongst the children. In my own family, one case occurred; and, out of eight incisions, four were perfectly successful. Therefore, I cannot agree with Dr. Underhill, that his case proves his point—that the vaccination virus so permeated the mother's system as to render the child insusceptible to successful vaccination. Would it not be well if Dr. Underhill vaccinated again, as required by the Vaccination Act, before certifying as to the insusceptibility of the child? I may mention, as, perhaps, a remarkable coincidence, that I have had two cases recently where the mother suffered from small-pox at the time of her delivery; and in neither case (one child is more than two months, the other six weeks old) has the child, up to the present, shown any symptom of small-pox or other illness. E. T. BURTON, Birmingham.

IDIOPATHIC ANÆMIA.

I HAVE read with much satisfaction, in the JOURNAL of November 28th, the paper on this singular disease described by Dr. S. Wilks of Guy's Hospital. It recalls vividly to my mind a case which I had under my care some five years ago, and in which I was greatly interested both personally and professionally. The subject was a gentleman "about the middle period of life", "large and bulky", with a strongly marked tendency to accumulate fat. I write under inverted commas; and indeed, in order to describe very clearly my case, it would only be necessary to quote almost *verbatim* the text of Dr. Addison's treatise, which with wonderful accuracy depicts the history, signs, and symptoms which presented themselves to me.

The advent of the disease in the case to which I refer was slow, insidious, and undecided. He was in the beginning very ill one week, the next comparatively well. Gradually he became pale, waxy, and without a vestige of colour. His pulse was slow, soft, and compressible. The least excitement or bodily exertion painfully distressed him with palpitation and dyspnoea. He lost appetite, and finally died out after a few days' confinement. His illness extended over twelve months, during which period he had all the advantages which easy circumstances could give, in the way of travel, change of scene, etc. He had also the best professional assistance this city could afford, and, in addition, the advice of Sir Thomas Watson, whose letters to me on the subject are before me, and who "could find no cause in him", his

heart-sounds being right, "his lungs, liver, and kidneys sound". Sir Thomas was inclined to attribute the origin of the patient's symptoms to a severe shock occasioned by the somewhat sudden death of an elder brother from heart-disease (pericarditis), arising in the course of Bright's kidney. For myself, I never hazarded a diagnosis, as in point of fact I was unable to classify or name the disease, although I conjectured the existence of some splenic lesion. One of the few variations in my case from Dr. Addison's description was, that some wasting and loss of flesh took place in the latter stages of the illness, and that the intellectual faculties remained unclouded up to almost the moment of dissolution. I will not detail the varied treatment adopted; but I may state generally that my patient derived not the least benefit from drugs or any of the many agents which were so fully availed of. The disease progressed with equal step, uncontrolled to the end. Unfortunately, no examination was made *post mortem*—always a difficulty in private practice, and especially so in this instance, as decomposition set in with unusual rapidity. RICHARD W. EGAN, L.R.C.P., L.R.C.S.I., Dublin.

OBSTETRIC MEMORANDA.

PEELING OF THE EPIDERMIS IN A LIVING FŒTUS.

THE following case seems to me to be of interest in a medico-legal aspect, and worthy of a short notice.

M. W., aged 35, married twelve years, mother of one child, aged 11, was last unwell February 25th to 28th, 1874. She expected her confinement the first week in December, but delivery was delayed until December 19th, at 1.20 P.M., when a living male fœtus, weighing eight pounds, was expelled. It was apparently still-born, though the cardiac pulsation was evident from the first; but, after efforts had been persevered in for five or ten minutes, respiration was established, and the child cried vigorously. It presented a dusky blue appearance; but what in the first instance led me to believe that death had taken place some days at least, was the condition of the epidermis, which peeled off readily from the whole surface of the body, coming off in large flakes as if maceration had taken place. The nurse, a woman of considerable experience, stated that she had never seen a similar instance. The epidermis was more adherent in some parts than others, but peeled readily; and when the child was washed and dressed, none but a small portion between the fingers and toes and in the concha of the ear remained. The child cried, passed urine, took food, and seemed to be doing well; but about 2 A.M. the following morning the nurse noticed that the breathing was unnatural. A warm-bath was given, but within an hour the child died, the surface of the body being almost purple.

Churchill says: "The peeling of the epidermis is a conclusive proof of the death of the fœtus." Dr. Barnes, in his *Obstetric Operations*, speaks of "the coming away of epidermis and hairs" as a certain sign. Dr. Leishman also "regards peeling of the skin as a certain proof of the death of the fœtus"; and, indeed, nearly all obstetric authors agree upon this point. I have never before met with a similar case, nor have I been able to find the record of any such; and for this reason I send these brief notes for publication. A. W. EDIS, M.D.,

Assistant Obstetric Physician to the Middlesex Hospital.

THE INDUCTION OF PREMATURE LABOUR.

I QUITE agree with Dr. Swayne, that he has given a "faithful record" of his experience in inducing premature labour, and I most readily allow he is deserving much praise for the honest manner in which he has done so. To this record I have never demurred, my objections being to the conclusions at which he would have us arrive from his narration of cases; and, as I do not think he has satisfactorily answered my objections, I still fail to see that the claim he makes in his original communication, that the new method of treatment advocated by him is "very superior" to the "old-fashioned method", is at all borne out by his statistics. I would also remind him, that a vague charge of "captious criticism" will not do away with the facts shown by his own statistics, and that his plea, of his method not being worse than mine, is but a sorry proof of its being "much superior".

That Dr. Swayne should cite Dr. Barnes as an authority in support of his opinions, is very astonishing, as I find in Dr. Barnes's Lecture on the Induction of Premature Labour (pp. 359 and 360), in his work on *Obstetric Operations*, that he says, when speaking of the use of spongetents, etc.:—"There is no doubt labour can be induced by those agents. But it appears to me that their use to provoke labour is not based on a rational view of the physiological or clinical history of the process. I agree with Lazarewitch, that irritants applied to the cervix are slow and

uncertain. And I believe that in most cases some further means, such as rupturing the membranes, will be necessary."

I am of opinion that this sweeping condemnation is fully substantiated by Dr. Swayne's faithful narration of cases; and, although I had never, until within a few days, seen Dr. Barnes's work, it fully bears out my objections to Dr. Swayne's claims of a much "superior method".

I will conclude this, my last communication on the subject, by thanking Dr. Swayne for his record of cases, as I feel convinced it will be useful in warning all who read it, to most religiously avoid the use of sponge-tents, etc., for the purpose of inducing premature labour.

STEPHEN CLOGG, Looe.

REPORTS

OF

MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

KING'S COLLEGE HOSPITAL.

CASE OF EMPYEMA TREATED BY REPEATED ASPIRATION AND SUBSEQUENTLY BY DRAINAGE: RECOVERY.

(Under the care of Dr. PLAYFAIR.)

Ernest M., aged 7, a delicate rachitic child, was admitted into Pantia Ralli ward, on June 1, 1873. At the time of admission, he was suffering from general feverishness; temperature, 103 deg.; pulse, 160. He had slight cough and delirium at night. On auscultation, there was nothing to be detected beyond feeble respiration over the greater part of the right lung. On June 3rd, dullness on percussion was detected at the right base, and the respiration there was distant and feeble; temperature, 104 deg.; respiration 60. From this date the dullness rapidly increased; on the 11th, there was nearly absolute dullness over the whole of the right lung, and the child's breathing was rapid and much embarrassed. On the next day, aspiration was performed, and thirty-two ounces of thick yellow pus were withdrawn, with great relief to the general symptoms. Next morning, the patient's temperature had fallen to 98.3 and there was fair resonance as low as the angle of the scapula. On the 14th, the dullness had again increased to an inch above the angle of the scapula. Between this date and June 24th, three successive aspirations were performed, at which eighteen, seventeen, and sixteen ounces of pus were drawn off. After each operation, the general symptoms were temporarily relieved, but the chest again began to fill with great rapidity, and, on the 24th, a bulging fluctuating swelling was observed between the sixth and seventh ribs. The attempt to treat the case by aspiration was, therefore, abandoned, the abscess was opened, and a flexible tube inserted, the other end of which was placed in a vessel of water under the bed, in the manner described by Dr. Playfair in his paper on "The Treatment of Empyema in Children" (Obstetrical Society's *Transactions*, vol. xiv). The effect of this was highly satisfactory; the patient's temperature, which had previously ranged from 101 deg. to 102 deg., immediately fell to 98 deg., and his respiration became more natural; from one to two fluid ounces of pus were daily discharged through the tube, without any apparent entry of air into the pleura; the child now ate and slept well, and improved rapidly in every respect. Things went on thus until August 23rd; the child gained flesh daily, and the amount of discharge gradually diminished to about a drachm *per diem*. On that day the tube came out, and, as there was now a free entrance of air, it was thought better to make a counter-opening, and to insert an ordinary drainage tube. This was accordingly done; and a weak iodine lotion (five minims of the tincture to an ounce of water) was injected through the tube every two or three days. On September 1st, the discharge had almost entirely ceased, and the drainage-tube was removed. The child was now quite convalescent; there was hardly any flattening of the chest-walls, and there was good respiration audible over the whole of the affected side. He was discharged on November 1st. Dr. Playfair remarked that this was a most satisfactory termination to a most unpromising case of empyema in a delicate rickety child. Although he himself was convinced of the superiority of free and continuous drainage to any other plan in all cases in which the hope of absorption was abandoned, he was desirous, in this case, of giving a fair trial to the method of repeated aspiration, strongly advocated by Bouehut. It was, however, a complete failure, the pus rapidly reforming, and eventually threatening to form a spontaneous opening at an unsuitable position. This was a serious calamity when the opening occurred too high in the chest to allow a free exit, and was often followed by very serious deformities, the collection of putrid

pus in the depending part of the pleural cavity, and a very protracted convalescence. Hence the method of continuous subaqueous drainage he recommended was adopted, and with great success for a month, when eventually a counter-opening was made, for the purpose of facilitating the use of iodine injections. The termination of the case was all that could possibly be desired, the resulting deformity was almost nil, and the case contrasted most favourably with those too common instances of empyema in which a free opening was made into the pleural cavity, either by incision or spontaneous opening, in which a cure only took place after many months of exhausting suppuration, and with marked flattening and deformity of the chest-wall.

GENERAL HOSPITAL, BIRMINGHAM.

CASE OF TRAUMATIC STRICTURE OF THE URETHRA: HOLT'S OPERATION: RECOVERY: CLINICAL REMARKS.

(Under the care of Mr. BARTLEET.)

[Brief Notes by Mr. SKIPWORTH, Resident Surgical Assistant.]

THOMAS MORGAN, miner, aged 16, was admitted, suffering from incontinence of urine, into the medical wards of the hospital. Mr. Bartleet was asked to sound him for stone, and was unable to pass a sound or even a No. 1 catheter, on account of a stricture situated half an inch in front of the bulb. The boy was removed into a surgical ward, and the following history was obtained. About four years ago, he was leading a horse, which took fright, and dragged him for some distance along the ground. His leg was broken, his genital organs much bruised, and there was hæmorrhage from the urethra. The catheter was used for three weeks. Ever since, cold had caused difficulty and pain in micturition; and for the last eighteen months he had been unable to retain his urine day or night. He never passes urine in quantity, but only *guttatim*.

September 3rd. After repeated trials, a No. 1 silver catheter was passed, and retained for one hour. It would have been retained longer, but the eye was obstructed by clot.

September 7th. A No. 2 passed; and during the next three weeks the stricture was gradually stretched up to No. 5.

On October 3rd, Holt's operation was performed under chloroform, the medium-sized dilator being employed. Immediately after the operation, a No. 10 catheter was passed and withdrawn. The performance of the operation was not followed by pain or rise in temperature, the only *contretemps* being retention of urine, which necessitated the use of the catheter.

October 31st. The urethra was found to readily take a No. 12 catheter, and the boy was dismissed cured.

CLINICAL REMARKS BY MR. BARTLEET.—It is most important, in all cases of incontinence of urine, to examine the whole of the urinary apparatus that is within reach, and also the urine itself; for, while we occasionally meet with cases of incontinence which appear to be simply owing to "habit", without doubt the majority are caused by irritation of some part of the urinary tract; such irritation being due to a tangible and preventable cause, such as irritating urine, the presence of calculus, an unnaturally narrow meatus, or, as in the present case, the presence of a stricture. Stricture is an uncommon affection in childhood, and, when met with, is usually due to injury. In this case, the injury to the urethra was not accompanied by cicatrices in the perineum or scrotum; and the history of the case tells us that, at the time of the accident, the integuments were not wounded. Hence the idea of a stricture never occurred to me until I sounded for stone.

I have always found traumatic strictures most difficult to deal with. In many cases, they are complicated with fistulous openings, and then there is a choice between dilatation in some form and external urethrotomy. In the present case, the absence of any fistulous opening seemed to point to an operation for the relief of the stricture in which the perineum was not incised. The universal failure in my hands of dilatation in the cases of traumatic stricture which have occurred in my practice, and the marked tendency to recurrence exhibited by this stricture in the early part of the treatment—that is, while it was being dilated to the size of a No. 5 catheter—induced me to perform Holt's operation, an operation which I have now performed many times with invariably good results. In this case, the operation was performed with ease, and was followed by no inconvenience save retention for two days, and by no symptoms which gave the slightest anxiety.

In performing the operation, two or three points are important: firstly, to be certain the instrument is in the bladder. The shape of the Holt's dilator renders its introduction a little more difficult than that of a catheter. The only way of being certain of this most important point is to see the urine flowing through the hollow staff of the instrument. The splitting of the stricture should be ensured by a *smar-*

upon the travelling rod. If this be struck timidly, or pushed, the structure will be stretched and not torn, and will be much more likely to repair. Lastly, it is important to see that everything is freely stretched or torn, by revolving the instrument on its own axis in the apophysis, where it should move with perfect freedom.

As regards the after-treatment, in the present case little was required beyond the occasional passage of a catheter. Occasionally, doses of quinine are necessary to prevent rigors, or of opium to relieve pain and procure sleep.

Finally, I may express my conviction that Holt's operation for stricture presents us with a safe and sure mode of treatment for those cases of stricture which tend to recur under the treatment by ordinary or by continuous dilatation.

CUMBERLAND INFIRMARY.

EXOSTOSIS OF THE LOWER END OF THE FEMUR: REMOVAL: RECOVERY.

(Under the care of Dr. MACLAREN.)

SARAH H., aged 17, dressmaker, was admitted on May 6th, 1874. Five years ago, a piece of paving-stone fell upon her right knee, causing some pain and swelling, which kept her in bed for a fortnight. The pain disappeared for a time; but the swelling continued slowly to increase. About two years ago, she again suffered pain; and since then walking had always brought it on severely. Lately, it had sometimes lasted for forty-eight hours continuously; and for the last four months she had been unable to work. On examining her right thigh, a hard rounded tumour, with apparently a very broad base, was felt attached to the lower end of the femur at its inner side, a little above the patella. The right thigh measured an inch and a half more than the left at the position of the tumour.

On June 6th, the patient was placed under chloroform. Dr. MacLaren exposed the tumour by an incision five inches long, and cut through its base with a chain-saw. The operation was done under carbolic spray, and the wound was dressed antiseptically. In a fortnight, the deep wound was healed; and, on July 2nd, cicatrization was nearly completed. Up to this date, the wound had been kept quite aseptic; but it was now so nearly well, that it seemed unnecessary to incur any longer the extra trouble which antiseptic dressings involve, and water-dressing was substituted. As no improvement took place under this treatment, various lotions were applied, but the result was the same: an indolent ulcer remained at each end of the wound. On August 13th, antiseptic dressings were resumed; and, on September 2nd, the patient was discharged with the wound quite healed.

	Temperature.			Pulse.		
	M.	E.	F.	M.	E.	F.
June 9	98.4	88	...
„ 10 ...	101	100	...	128	104	...
„ 11 ...	100.2	101.4	...	132	128	...
„ 12 ...	99.6	100	...	106	120	...
„ 13 ...	98.6	99	...	76	104	...
„ 14 ...	99	99	...	78	88	...

Afterwards normal.

The exostosis was composed of cancellated bony structure, containing much fat, and partly covered by cartilage. It measured $2 \times 1\frac{1}{2}$ inches. The attachment to the femur measured $2\frac{3}{4} \times \frac{1}{2}$ inch.

REMARKS BY DR. MACLAREN.—The removal of an exostosis is an operation involving considerable danger to life. "Diffuse suppuration in the intermuscular spaces, erysipelas, and pyæmia, are very liable to follow such operations." In reference to this individual case, a surgeon of very extended experience said that amputation of the thigh at the lower third would involve less risk. The justifications for interference were, that the girl was incapacitated by the tumour from earning her living, and that it caused her much suffering. There was, in addition, the hope that the above-mentioned dangers could be avoided by carefully carrying out the antiseptic system of dressing; and the patient never had a symptom after the operation that caused a moment's anxiety.

Last May, Dr. Chiene read a paper to the Medico-Chirurgical Society of Edinburgh on a case in which an exostosis was accidentally fractured and disappeared entirely within a year after, and he proposed intentional fracture as a means of treatment. On July 8th, Mr. Maunier fractured an exostosis subcutaneously with a pair of gas-fitter's pliers. In this instance, the tumour has become reunited to the femur, but in a more convenient situation; and the cure by absorption has not taken place. As it seems probable that subcutaneous fracture would obviate even more effectually than antiseptic dressing the known dangers of removal of these tumours, and as, in all probability, reunion

could be prevented by frequently moving the separated mass, it appears to be deserving of further trial; I have mentioned it in order to point out that the feeling of the tumour having a broad base is sometimes deceptive. In this case, when examined through the tissues, it seemed almost sessile, whereas it had really a small attachment to the femur, and curved downwards, a considerable portion of it lying nearly in contact with the bone. I think it could have been readily fractured.

REVIEWS AND NOTICES.

ON FUNCTIONAL DERANGEMENTS OF THE LIVER; being the Croonian Lectures delivered at the Royal College of Physicians in 1874. By CHARLES MURCHISON, M.D., LL.D., F.R.S., etc. Pp. 182. London: Smith, Elder and Co. 1874.

THESE lectures were pretty fully reported in our pages at the time of their delivery, but are now reprinted in a very handsome little volume, with illustrations on wood, and the latest additions and emendations of their author. We can all of us remember the crude pathology of a bygone age, which attributed nine-tenths, if not more, of the maladies "that flesh is heir to", to the largest gland in the body. A consumptive patient had an attack of pleurisy; he was told, without further examination than a hasty peep at his tongue, "Your liver is out of order". Another was, perhaps, suffering from syphilitic periostitis of the dextral ribs, and the same explanation of his symptoms, and too often the same treatment also, was made to do duty on both occasions. Of late years, we may truly say; "nous avons changé tout cela"; and Dr. MURCHISON tells us that we have changed too much; for the tendency nowadays seems to be to ignore the very numerous and important functions of the liver, and the part its derangements play in the various disorders and maladies from which we or our patients suffer. It would, perhaps, be difficult—at least in England—to find another physician so well qualified, not only by general attainments, but by previous studies of the same subject, as the author of these lectures; for we cannot forget that the Croonian lecturer translated for the New Sydenham Society the now classical work of Frerichs on *Diseases of the Liver*. His own well-known book on *Errors*, and his Lectures on Medicine, with the whole bent of his mind and the nature of his practice, eminently qualify him to write on a subject which, perhaps, more than many others, requires breadth and catholicity in its treatment. If we compare the teachings, *ex cathedra*, of our student days, on the liver and its derangements, with the little treatise before us, we cannot but see that pathology is making vast strides. The older professors, whether of medicine in the wider sense, or of its pathological department, would be staggered, and almost affrighted, the moment they opened its pages. The first thing that strikes the eye, after the dedication to Sir Wm. Jenner and the table of contents, is another table, of a full page in length, of chemical equivalents, commencing thus:

Albuminoids (Lieberkühn)	$C_{72}H_{112}N_{18}SO_{33}$
Excretin	$C_{78}H_{115}NO_2$
Tauro-cholic acid	$C_{26}H_{43}NO_8S$
Glyco-cholic acid	$C_{26}H_{43}NO_8$
Cholic acid	$C_{26}H_{43}O_8$
Taurin	$C_{2}H_7NO_3S$

And in similar style through twenty-eight organic compounds. It thus becomes evident, that chemistry is taking its proper place in our studies of life and of disease. It is not a little credit to England, that our countrymen, the elder Marcet, and Velloly, and Bostock, led the way in this department of analysis, when even in Germany such things were as yet but little thought of. This chemical prelude introduces us to the dominant idea on which the author gives us many pleasant and interesting variations in the subsequent lectures. For it is the functional derangements of the liver of which these Croonian Lectures treat: the coarser anatomical changes, such as those induced by cancer, syphilis, abscess, and the like, are scarcely mentioned, if at all. The working liver, with the causes of the creaking and failure of its machinery, is the subject of Dr. Murchison's eloquence and research; and, after a brief account of the founder of these lectures,* nearly forty pages are devoted to the functions of the liver in health. What these are, is briefly summarised at page 44, as follows.

* We learn from this that Dr. William Croone was a native of London, educated at Emanuel College, Cambridge, became F.R.C.P. in 1675, and Censor in 1679. He was Professor of Rhetoric at Gresham College, and Secretary of the Royal Society. In 1679, he lectured on Anatomy at Surgeons' Hall; and died in 1684. He planned the two lectureships (this, and the one at the Royal Society) which bear his name; but his will containing no provision for their endowment, we really owe them to the munificent bequest of his widow, *née* Lorimer, afterwards Lady Sadleir, by a second marriage.

"1. The formation of glycogen, which contributes to the maintenance of animal heat, and to the nutrition of the blood and tissues, and the development of white blood-corpuscles ;

"2. The destructive metamorphosis of albuminoid matter, and the formation of urea and other nitrogenous products, which are subsequently eliminated by the kidneys: these chemical changes also contributing to the development of animal heat ;

"3. The secretion of bile, the greater part of which is reabsorbed, assisting in the assimilation of fat and peptones, and probably in those chemical changes which go on in the liver and portal circulation; while part is excrementitious, and, in passing along the bowel, stimulates peristalsis and arrests decomposition."

For the proofs of nearly all this, we must refer to the book itself, only noting briefly one or two points regarding sugar and bile. It is clear from the note to page 10, that Dr. Murchison believes the liver to make sugar as well as glycogen—thus siding with Bernard and Flint. He also believes that the liver makes the whole of the constituents of bile, and that none of its peculiar elements exist preformed in the blood, thus agreeing with Frerichs. He thinks (for reasons stated in the text) that about forty ounces of bile *per diem* is a fair average amount for a man of eleven stone weight, which is Dr. Carpenter's estimate, founded on the data of several experimenters (Nasse, Platner, Stuckman, etc.) He also inclines to the belief that the hepatic artery furnishes most of the blood destined for the secretion of bile; a view which is confirmed by pathological records, some of which are given at page 40, and others are known to us.

After mastering the contents of these forty pages, the reader will not, we think, be surprised that a gland with such numerous and important functions should often become disordered and obstructed in its working, either primarily or by the derangement of other organs, and this very often, at least at first, with but slight change in its own structure of a kind to be recognised by the naked eye, or perhaps at all, by other than chemical tests. The remainder of the lectures is taken up with a consideration of these disordered functions, and the diseases in which they play a part. Formidable indeed is the list of these, and did we only see their titles we might suspect Dr. Murchison of exaggeration, for the list includes corpulency, and its opposite, emaciation; diabetes; which, "in fact, may be said to be, in most instances, a functional derangement of the liver", from (1) imperfect glycogenesis, or (2) an increased conversion of glycogen into sugar, or (3) diminished destruction of sugar; other wasting diseases, such, probably, as phthisis and waxy disease; many forms of dyspepsia; lithæmia; gout; urinary and biliary calculi: kidney degenerations; perhaps those of the liver itself; local inflammations in other organs; degeneration of tissues throughout the body; derangements of the nervous system, including paralysis, convulsions and coma, and very often uræmia; jaundice; derangements of circulation, even including angina pectoris; skin-diseases, such as urticaria, eczema, xanthelasma, and pruritus; and disorders of respiration, no less serious than bronchitis and asthma.

We do not wish to misrepresent the author, and therefore hasten to state that the book by no means represents that all these diseases or symptoms are generally or invariably produced by badly performed functions of the liver, but only that these play an important part in the genesis of such maladies, and often form the starting point of severe mischief in distant organs. Those, however, who read the book need no apology, for on each and all of these points the Croonian lecturer has abundance of material. According to Dr. Murchison, the principal causes of these functional derangements, when primary, are the following. *Errors in diet*, including the abuse of alcoholic liquors. On this point, the lecturer's language is clear and unmistakable in its notes of warning; at page 149 he says: "But of all ingesta, the various alcoholic drinks are most apt to derange the liver. They do so in two ways. *a.* They may cause persistent congestion of the liver. Even small quantities of alcohol in healthy persons produce a temporary hepatic congestion; but if alcohol be taken in excess, or too frequently, the congestion of the liver becomes permanent, and the functions of the organ are deranged. Like results may ensue from comparatively small quantities in certain persons, who may be said to have a constitutional intolerance of alcohol. Of course, if the congestion be long maintained, structural disease may follow. *b.* But wines and other alcoholic drinks often cause derangement of the liver which a corresponding quantity of pure alcohol would not produce, and which, in fact, cannot be accounted for by any one ingredient of the offending liquid; neither by the free acid, the ether, the salts, gum, sugar, or extractive matter. *This general rule, however, I believe, holds good, that the injurious effect of alcoholic beverages upon the liver increases in a direct ratio with the amount of sugar *plus* alcohol which they contain. It would seem, indeed, that a mixture of alcohol and sugar pro-

duces injurious results, which would not be caused by the admixture of a much larger quantity of sugar, or of alcohol alone, with the food. In accordance with this view, the alcoholic drinks which are found by experience to be most apt to disagree with the liver, are malt liquors of all sorts, but especially porter, and the stronger forms of mild ale, port wine, madeira, tokay, malaga, sweet champagne, dark sherries, liqueurs, and brandy; whilst those which are least likely to derange the functions of the organs are claret, hock, moselle, dry sherry, and gin or whisky, largely diluted." (See also p. 162.) 2. *A deficient supply of oxygen.* 3. *A high temperature.* After instancing tropical climates and hot seasons, he says, "Experiment has shown that one of the effects of a high temperature upon the lower animals is to produce a degeneration of the parenchyma of the liver, its secreting cells becoming filled with miniature granules, and presenting appearances similar to those found after death from febrile diseases." (*Pathological Transactions*, 1873, vol. xiv, p. 266.) 4. *Nervous influences.* Dr. Murchison agrees with Dr. Budd, "that mental anxiety or trouble has great influence in the production of gall-stones", and has "repeatedly known attacks of biliary colic from gall-stones excited by some sudden emotion". He even thinks, that the cases of cancer dating from indigestion following protracted grief or anxiety, are "far too numerous to be accounted for on the supposition that the mental distress and the cancer have been mere coincidences". 5. *Constitutional peculiarities*—often inherited. 6. *Poisons* of various kinds: malaria, other fevers, phosphorus, articles taken as food, mineral poisons, notably lead.

For the gouty condition of blood, which he largely attributes to the liver, he proposes the name of *lithæmia* as more elegant than uricæmia, proposed by Austin Flint. Whilst not entirely ignoring the existence of *cholesteræmia* (or a morbid condition of blood due to the accumulation of cholestearine in that fluid), for which this eminent American contends, Dr. Murchison urges strongly several reasons for believing that the fatal symptoms often met with at the termination of liver-diseases are really due to uræmia, or the accumulation of urea in the blood; one of the chief being that clinically the two conditions are almost, if not perfectly identical (p. 121, and elsewhere); whilst he thinks that other morbid matters besides urea, or biliary acids, may give rise to some of the symptoms. The cases of intermittent pulse, depending probably upon lithæmia, due to deranged liver (pp. 126-132), including also the almost opposite condition of pulsatile aorta, are of great interest, whatever our views as to their causation.

The conclusion of the book (p. 160 to 161) is occupied with the important question of the treatment of these functional disorders, under the headings of—1. *Diet*; 2. *A free Supply of Oxygen*, where, by the bye, no mention is made of ozonic ether or peroxide of hydrogen; 3. *Aperients, Cholagogues*, amongst which we are glad to see that he has a good word to say for the oft-abused *Mercurials*, justly preferring clinical experience to experiments of a somewhat doubtful nature made on inferior animals; 4. *Alkalies*, which, we need scarcely say, rank high in our author's esteem; 5. *Chlorine, Iodine, and Bromine*, and their compounds; 6. *Mineral Acids*; and 7. *Tonics*; lastly, *Opium*, showing its usefulness in diabetes, used thus sixty years ago by Sir B. Brodie (quoted in note to page 181), and explaining why it is often counter-indicated in hepatic diseases, although, contrary to common opinion, it is almost certain that opiates rather increase than diminish bile-formation.

Those who read this sketch of hepatic therapeutics will, we think, share our regret that this part of the work was not extended to a greater length, as we hope it will be in a future edition. If there still be any who share with Molière and our own Byron in their professions of contempt for physicians, and in their opinion that medicine is purely a hypothetical art, we think they could not do better than read and study this little book of Dr. Murchison's, in which they will see "things new and old", but all carefully digested, and, what is more, hypothesis carefully severed from matters of fact. Our regret at the brevity of this volume, which is eminently readable, in spite of its containing hundreds of facts and almost as many references to English, American, and continental authors, is assuaged by the hope of future and enlarged editions; but, whether republished in its present or in an enlarged form, we trust future editions will contain an index.

CROUP IN ITS RELATION TO TRACHEOTOMY. By J. SOLIS COHEN, M.D., Lecturer on Laryngoscopy and Diseases of the Throat and Chest in Jefferson Medical College. Pp. 78. Philadelphia: Lindsay and Blakiston. London: Triebner.

DR. COHEN is well known in England through his excellent work on *Diseases of the Throat*, and we have much pleasure in calling attention to his more recent contribution. His former book, though abounding in useful information, was somewhat defective in arrangement; but his

essay on *Tracheotomy* is not less perspicuous in plan than full of valuable matter. Dr. Cohen's monograph is based on statistics drawn from French, German, English, and American sources, the figures being subjected to very careful analysis, and not reduced to those averages which often render the numerical method fallacious.

The indications for the operation, the best mode of opening the windpipe, the employment of anaesthetics, the after-treatment of the disease and of the surgical wound, the casualties which prevent recovery, the period at which a fatal issue may be looked for or a cure anticipated—are each discussed in a thoroughly lucid manner. The most important deductions of the author are:—That there is no insuperable contraindication to tracheotomy in croup; that anaesthetics are admissible, but must be administered with great caution; that the incision should be made as near the cricoid cartilage as possible, after careful dissection of the superjacent parts; and that the tube should be dispensed with as soon as possible. Finally, Dr. Cohen remarks that assiduous attention should be bestowed on the after-treatment, especially that of the wound; and that a skilled attendant should be within a moment's call for the first twenty-four or forty-eight hours immediately following the operation. We cordially agree with this last proposition, and believe that many lives would be saved if it were more generally acted upon.

Want of space will not permit us to do justice to this interesting and instructive volume; but, since tracheotomy is an operation which any medical practitioner may be called upon to perform at a moment's notice, we strongly recommend the work to the profession, as a guide at once philosophical and practical.

THE PRESENT STATE OF THE ARMY MEDICAL SERVICE AS A LIFE CAREER FOR THE SURGEON. By EDWARD HAMILTON, A.B., M.D., etc. Dublin: Fannin and Co. London: Longmans. 1875.

UNDER this title, Dr. HAMILTON has published a pamphlet of which we heartily applaud the intention. It is laborious, spirited, and in the main a just picture of the disadvantages of a military medical career in the present state of the service. The author has largely borrowed from material furnished in our pages; and it would, perhaps, have been more gracious, had he not topped and tailed documents so as to make their source unrecognisable. We trust, however, that his pamphlet will be as serviceable as its author desires. In order, however, that it may have the desired authority, it should be withdrawn from circulation and subject to revision of its figures, for, in some all-important matters of calculation, it contains the most extraordinary blunders. Thus he makes his figures prove that, if the Government were to promote surgeons at twelve years, instead of after fifteen years' service, to be surgeons-major, it would make very little difference in outlay—only £2,538 *per annum* for the whole department, taking a course of eleven years. Even in his own way of calculating, he has made a mistake in his figures, owing to not having put rightly the difference of the surgeons' and surgeon-majors' allowances; and he has made the mistake to the disadvantage of his own argument, for, according to his mode of calculation, with right figures, the cost to the Government would be only £1,873 *per annum* for eleven years, instead of £2,538. But, unfortunately, there is an error of a more serious kind at the bottom of his whole arithmetic; for the real cost to Government of promoting men at twelve years instead of fifteen years would be £113,700 for eleven years, or £10,335 for each year. Thus it is five times Dr. Hamilton's own estimate, and five-and-a-half times what that estimate would have been had it been correctly worked out even according to his own method. Even this £10,335 *per annum* might be not too much for Government to spend on the department; but it is better, at any rate, that false calculations, which will not bear rigid investigation, should not be urged on the Government. We hope, therefore, Dr. Hamilton will adopt our suggestion and at once revise his figures.

NOTES ON BOOKS.

We welcome the completion of the third edition of the *Micrographic Dictionary* (J. Van Noort). It is an invaluable repository for students of the microscope, and the twenty-one parts now published form a volume which is unrivalled in its interest and encyclopaedic value. No lover of general micrography can well dispense with this well compiled and beautifully illustrated book.

The issue of Sowerby's *British Wild Flowers*—a book of classic excellence—is also progressing satisfactorily in the hands of the same publishers. We have before us Parts 7, 8, and 9. The drawings, figs. 481 to 720, are delightfully drawn and coloured. For the field-botanist, this book is a treasury of useful and pleasing reference.

BRITISH MEDICAL ASSOCIATION: SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, JANUARY 9TH, 1875.

THE REPORT OF THE COMMISSIONERS IN LUNACY.

THE twenty-eighth report of the Commissioners in Lunacy, which is dated March 31st, 1874, opens with a short statement of the tragical circumstances under which one of their number met his death, while engaged in the discharge of his duty. The sad end of Mr. Lutwidge, which resulted from a wound of the temple, inflicted by an inmate of the Fisherton Asylum, created a feeling of painful sympathy throughout the country at the time of its occurrence, and is remembered now with genuine sorrow, not only by his colleagues, who pay a graceful tribute of respect to his memory, but by all those who were brought into official or friendly contact with him. Cordial and sincere, humane and magnanimous, Mr. Lutwidge seems to have had much of the modern Bayard in him. He conciliated those who were inclined to be hostile, gained the good will of the indifferent, and endeared himself to his more intimate acquaintances. Such a life as his could ill be spared; and it is difficult to refrain from harbouring vindictive feelings against that criminal lunatic who took it, and who, having been maintained for twenty-seven years at the public cost, thus robbed the public of a valuable servant. The allegation of the Commissioners regarding that criminal lunatic, that he was accountable for his actions when he killed Mr. Lutwidge, raises some serious questions as to the boundaries of responsibility, criminal and civil, and as to the degree in which the insane ought to be amenable to punishment. Without entering here upon such extensive topics, we may point out that the murder of Mr. Lutwidge, by a lunatic who had been for years regarded as harmless, brings into vivid conception the risks run by those who have habitually to mingle with the insane. A lunatic asylum is indeed a magazine of explosive materials, and both courage and caution are required of its custodians.

Having briefly and appropriately referred to the loss of their coadjutor, the Commissioners proceed to describe their operations for the year, and to take a general survey of the lunacy of the kingdom. That survey is in some respects alarming, and in others reassuring. It is alarming, because it reveals that insanity is steadily increasing amongst us, and that we are still without definite information as to the causes of that increase, or the means by which it may be met and arrested. It is reassuring, because it satisfies us that the provision made for the insane in this country is being gradually improved, and that the Commissioners are vigilant over everything that concerns the welfare of that afflicted class that has been placed under their supervision. Abundant evidence of quiet unostentatious progress is furnished by the report before us. There can be no question that the twelvemonths' work of the Commissioners—and hard work too—here summed up, has been productive of widespread benefit; and that their exertions, seconded by those of the medical officers of our lunatic hospitals, are daily augmenting the usefulness of these institutions, and making them more than ever patterns for imitation to the rest of Europe, and, but for fear of the consequences, we should add to America also. There can be no question that the Commissioners execute their trust in an efficient and skilful manner. They have hit upon the art of happily combining central authority with local liberty. Stringent and uncompromising in the universal en-

forcement of certain well established principles, they are indulgent, even to individual caprice, where room for experiment and doubt remains. No better testimony can be offered to the sagacity of their policy, than the unrummuring way in which it is everywhere received and acted upon. Their counsels are almost invariably and promptly adopted; and they are not, like other boards that might be mentioned, embroiled in incessant and rancorous controversies with subordinate authorities and recalcitrant officials. Differences of opinion, as is inevitable, from time to time arise between the Commissioners and those whom they have to direct and advise, but these differences are not aggravated into open feuds, and generally end in a diplomatic triumph for the Board at Whitehall. Their annual Blue Book is a monument of the discretion of the Commissioners. It is just such a Blue Book as Lord Palmerston would have approved, if he had been in the habit of reading these official incubations. In it the Commissioners do not commit themselves to neat theories, nor engage in vague speculations, but are content to deal in a straightforward and practical spirit with the problems which have come before them during the year. They avoid all statistical strategies and social puzzles, but clearly set forth the condition of the establishments which they have inspected. They administer censure with a justice and calmness that leave no room for reproach, and are not niggardly of praise where it is deserved.

As the total number of lunatics, idiots, and persons of unsound mind in England was increased by 1731 during last year, we are not surprised to find the Commissioners reporting the erection of new asylums, and the enlargement of already existing ones. At Whittingham, in Lancashire, a most complete and well-balanced asylum, intended to accommodate 1100 patients, and built from designs supplied by an able member of the medical profession, Mr. Holland, has been formally opened; and at Chartham, in Kent, a new asylum for 640 patients is now in process of construction. At the Norfolk, Somerset, and Surrey County Asylums, and at that for the City of London, considerable extensions have been effected, and at several other asylums enlargements are in prospect. More pleasing to contemplate than these enlargements, however, are the improvements which have been carried out at various establishments, and which have obviously been carefully designed to enhance their usefulness, and to meet the requirements of science and humanity for the treatment of mental diseases. A new chapel has been added to the asylum for the county of Cumberland, and a Turkish bath to that for the county of Glamorgan. The Worcester Asylum has been setting its drains in order, and has acquired two new general bath-rooms; while the Oxford Asylum has made better provision for the healthful employment of its inmates by the purchase of a plot of land, and has exhibited a wise forethought by the erection of a detached infirmary for infectious diseases. It is impossible to enumerate a title of the improvements which the Commissioners refer to, and which have not been confined to county and borough asylums, but have been distributed over registered hospitals, metropolitan and provincial licensed houses, and workhouses as well. Suffice it to note, that a spirit of improvement is abroad in our asylums, and that the manifestations of that spirit which are reported are all of a commendable kind. That they are so is due mainly to the influence of the Commissioners, who zealously oppose any tendency to improve backwards that may display itself, and always advocate sound and judicious reforms. We are glad to observe that they are imbued with a proper sense of the medical character of a lunatic asylum, and that they give their support to the scientific study of mental derangements. "We have the satisfaction of reporting", they say, "that the practice of making *post mortem* examinations of the bodies of patients dying in asylums continues, year by year, to be more generally adopted in nearly all our public asylums; the proportion of such examinations to the deaths having risen from a general average of 40 per cent. in 1869 to 61 per cent. in 1873". No opportunity of recommending an increase in an asylum medical staff, or of strengthening the hands of asylum medical officers in any laudable undertaking, is lost by the Commissioners.

There is what will probably prove a very useful appendix to this

report, consisting of the plans of three small asylums of approved and modern construction, and of a simple and economical form of ward for epileptic or suicidal patients. It is now thought desirable that patients of these classes should be subjected to constant supervision by night as well as by day, and the plan here published, is so arranged, as to afford facilities for carrying out that system. It strikes us, however, that the plan scarcely provides a sufficient amount of day-room space—only, apparently, about thirty-seven superficial feet per patient being allowed.

On five occasions during 1873 did the Commissioners feel called upon to direct the prosecution of those who had illegally detained and neglected, or ill-treated lunatics. On one of the cases, in which a prosecution took place, that of Vollans, we commented at the time, and did not hesitate to express the opinion that there had been a failure of justice. The Commissioners have taken the same view of the case, and, with great cogency, urge that the verdict was an extraordinary one, and much to be regretted in the cause of humanity.

NECROPSIES IN WORKHOUSES.

At the Portsea Island Union Workhouse, the Board of Guardians have lately suspended a medical officer, on the plea that he had made *post mortem* examinations without the sanction of the friends of the deceased; that he had performed *post mortem* surgical operations; and that he had removed certain portions of bodies from the mortuary, to wit, a liver and a larynx.

It appears that the Board of Guardians, at a previous meeting, had passed a resolution, to the effect that the surgeon should be permitted to make *post mortem* examinations, provided he first obtained the consent of the friends of the deceased. The defence of the medical officer was, that he had never made a *post mortem* examination without the consent of the friends of the deceased, and that he never performed surgical operations except upon unclaimed bodies; that the removal of portions from the mortuary was according to custom, the particular liver being a valuable specimen of disease for preservation, and the larynx requiring further investigation. After perusing the printed report of the case, we are of opinion that the first accusation was not proved on the part of the Board of Guardians. On the contrary, it is positively denied by the medical officer that he either made a *post mortem* examination, or even saw the body after death of an individual upon whom it was stated that such an examination had taken place. The Board of Guardians refuse to give the names of those from whom they derived their information. We are, therefore, bound to accept the evidence of the surgeon as correct. He states, in referring to one case in which it is alleged that a *post mortem* examination was made: "I declare that no *post mortem* took place." Referring to a second alleged necropsy, he says: "I never applied to the master to sanction a *post mortem* examination, because none ever took place; I never saw the body after death, and no thought of a *post mortem* ever entered my mind."

Unless the Board of Guardians will give the names of those from whom they derived their information, and are prepared to give a direct contradiction to the statements of the medical officer, they silently acknowledge that they have obtained information in a most careless and reckless manner; that they are totally incapable of weighing evidence; that they have committed a gross error in judgment; and that they have overstepped the bounds of their duty at an expense to, and with the temporary degradation of, one who, there is reason to believe, is a capable and efficient officer.

The Local Government Board, at Whitehall, have acquitted the medical officer of any improper motives in making the several *post mortem* examinations referred to, and have very properly reinstated him in his office.

We cannot, however, altogether agree with the decision of the Local Government Board in reference to the making of *post mortem* examinations in workhouses; and as their decision may be taken as a precedent in future mishaps between the Boards of Guardians and medical officers,

we think it requires further discussion. In the letter from the secretary at Whitehall to the Medical Officer of the Portsea Island Union Workhouse, the following notice occurs: "The Board consider that the workhouse is not a proper place for making *post mortem* examinations for this object" (in the interests of science); "and they must, therefore, require that in future you will not, in any case, make such examination, excepting by the direction of a coroner when holding an inquest, or the direction of the guardians for some special, urgent, and peculiar reason, which they may deem of such importance as to render such examination necessary. As a general rule, *post mortem* examinations ought only to take place in workhouses for the purpose of discovering the cause of death when it cannot be otherwise ascertained."

We are of opinion that no opportunity should be lost of making a *post mortem* examination either in private practice, or in hospitals, workhouses, and other public institutions. It is from the multitude of such examinations that facts are established which direct the progress of the science of medicine, and which ultimately lead to the saving of life. Some of the leading scientific men of our profession have held the office of surgeon to unions and workhouses; and in that capacity they never failed to associate the morbid anatomy, as seen in carefully made *post mortem* examinations, with the signs and symptoms of disease during life. It is to be regretted that men are rarely to be found who will trouble themselves with *post mortem* examinations; and most certainly should no unnecessary restrictions be placed upon energetic and scientific medical officers attached to infirmaries and workhouses where, of necessity, a large field for study is opened.

With regard to the performance of surgical operations upon unclaimed bodies, it is unnecessary further to discuss the matter on the present occasion; but, considering the dearth of subjects in the schools of medicine, it is to be considered a misfortune that, owing to the prejudice of some guardians, much material is lost which might be the means of simplifying the study, and of increasing the knowledge, of future generations of medical practitioners.

WHAT NEXT?

IN these days of multifarious charities, it is no easy matter to propose one which shall be altogether novel in its character. Yet this is what Dr. John M. Crombie has succeeded in doing, in a pamphlet entitled "A Plea for the Poor suffering from Painful Incurable Disease". Dr. Crombie, it seems, was for two years and a half resident medical officer at the Cancer Hospital, Brompton; and he observed that, in a great number of cases, the most important part of the treatment consisted in the administration of narcotics to relieve pain. But why, he asks, should poor people, who are incurably ill, come long distances, in rough third-class carriages, and wait for hours at a hospital, only to receive a small phial of laudanum? Would it not be a much better plan, and a much greater charity, to send it to them by post? This, in effect, is Dr. Crombie's proposed basis for a new charitable society. And if anodynes—"opium and its derivatives, with chloroform and its allies"—may in this way be sent to patients suffering from cancer, why may not other approved remedies be sent to other cases? Upon the certificate of two medical men, or of one medical man and a clergyman, Dr. Crombie proposes that medicines should be forwarded to all parts of the country; and contributions are earnestly solicited on behalf of the "United Kingdom Depot of Medicine, as the charity has been decided to be named, in explanation of its object of sending its medicines to any part of the United Kingdom". Dr. Crombie styles himself *Honorary Secretary*; but, as his is the only name which appears, we presume that the society is not yet constituted, and we trust that no one of rank or position will lend himself to such an unwise proposal. A society which springs out of the mode of practice in vogue at the Cancer Hospital will not be received with much favour by the profession; and, indeed, the only part of the pamphlet in which we concur is the comment upon the inutility of that institution. "The Cancer Hospital enjoys a multimium" (whatever that may be) "of the money, but it

remains for its medical staff to show a minimum of good done in the extraction of truth or utility for humanity."

Dr. Crombie's proposal rests entirely upon an absurd fallacy. "Let us reflect a moment," he says, "upon the thousands who die annually from this disease" (cancer), "and the many who must be sorely unprovided for, as there is nothing for them out of London but the union poorhouse, which is not very liberal in the supply of expensive medicines." Now, there is not much reason to complain of the union infirmaries. They are officered by very competent men, and the force of public opinion has done much of late years to make the guardians more considerate. But, over and above these, there are innumerable hospitals scattered over the country which Dr. Crombie entirely ignores. He implies that there are in London only two institutions capable of dealing with cases of malignant disease—the Cancer Hospital and the Middlesex Hospital; and we imagine the surgical staff of the latter will not thank him for the juxtaposition. He quite overlooks the numerous general hospitals and invalid-homes, both in the metropolis and in the provinces, where cancer can be far better treated than in the way he suggests. In dealing with the class of cases which Dr. Crombie seems to have in view, the proper course is to call out the kindly sympathy and assistance of neighbours and friends, and to allow the local medical man to direct their benevolence as he thinks best.

PROPERTY IN PRESCRIPTIONS.

THIS subject is one which has attracted less attention in this country than it has abroad. The common assumption, however, that a physician, in writing a prescription, loses all right of property in it, and that the chemist who copies it acquires the right of using it as he pleases, and the patient the right of perpetually disposing of it, does not everywhere pass unquestioned. A committee of the St. Louis Medical Society have drawn up a report which expresses very decided views on the subject. They say (*St. Louis Medical Journal*, December 1874):

A prescription is nothing more nor less than a written order or direction from the physician to the apothecary to furnish or compound certain medicines for the patient, to be used by him according to the written or verbal directions given him at the time. It is undoubtedly the property of the author, and neither the patient nor the apothecary acquires any right to make use of it, except for the case and purpose specified. It is merely a safe and convenient mode of communicating instructions from the physician to the druggist. Formerly, it was the general custom for the physician to dispense the drugs himself, and no prescriptions were needed. But, at the present day, in most cities and towns, the druggist prepares and furnishes the medicine. This arrangement is beneficial to both professions, as well as to the public, and from it arise certain implied contracts. When a physician sends a prescription to an apothecary to be compounded, there exists between them a tacit understanding or agreement that such prescription, when it is original with the practitioner sending it, shall not be made public. In such case, it would be neither honourable nor honest for the druggist to deprive the author of the benefit of it by dispensing it indiscriminately. The originator is the only person who would have the right to do so if he choose to exercise it. But the apothecary certainly does not obtain the same privilege by gaining a knowledge of the ingredients and proportions which he acquires in compounding the prescription.

The prescription is only a single order given the patient upon the druggist for use, at that time, unless otherwise directed by the physician; and if the patient have it repeated without further advice, he does so at his own risk, still we cannot prevent him from using a copy of said prescription as long as he chooses. Universal custom and legal decisions have sanctioned this right. The druggist who refills a prescription without an order from the doctor thereby assumes all responsibility for accidents that may accrue therefrom. He has really no equitable right to use the prescription in any manner without an order from the physician. Professor Ordonaux says: "But, although, as has been already shown, the party paying for the prescription has an undoubted property in the paper, and a right to the *personal use* of the formula, it is clear that he acquires thereby no absolute property in the latter. That he may use it personally as often as he pleases, cannot be doubted, for the use is precisely what he has purchased and paid for, but he has no right to give it to others."

The prescription, then, continues the property of the author, and the apothecary has no claim to it whatever, except as a record. The cus-

tom, however, of renewing prescriptions without consulting the physician has grown to be so common that it will be difficult to correct it, but by concert of action between physicians and druggists we may check the growing evil, and in a great measure do away with it. It has originated mainly from the desire of the patient to avoid the expense of consulting us a second time; but we, too, are very much to blame for it. Many medical men keep no record of their prescriptions, and when patients return to them, stating that the medicine which was ordered for them has acted so well that they wish to get it repeated, the doctor, not remembering the formula, directs its repetition. Others are actually too lazy to write a new prescription, and direct the patients to have it renewed. This practice has become so much abused that, unless we get our whole fee in advance, or direct the druggist not to repeat the prescription, we never again see the patient, who continues repeating his medicine until he is cured, and concludes that we have been well paid for our advice by a single fee. Agreement among druggists not to refill prescriptions, except upon a written order from the physician, would relieve them of all responsibility in case of a mistake or accident; would save them much trouble in hunting up old prescriptions; and, if the custom were general, would rather increase than diminish their business, whilst it would restore to us much that legitimately belongs to our profession. Liberality is one of the cardinal virtues of our profession, but it will hardly be expected that we should throw away our knowledge.

They recommend the following resolutions:

"That, as members of this Society, we are opposed to the dangerous practice of patients and druggists renewing a prescription without consulting its author to ascertain whether such medicine should be continued or not, for it is well known that many medicines have a cumulative effect, and thereby become dangerous and destructive."

"That we will favour legislation that will prohibit the dangerous practice of apothecaries renewing prescriptions without the authority of the physician, and that, until such legislation be effected, we earnestly request all pharmacists to restrain from repeating prescriptions as far as they can, without a written order or endorsement from the physician, and ask them to destroy all prescriptions after retaining them in their possession for thirty days."

"That, as the physician, as the originator of the prescription, acquires a literary property in the composition of the formula, belonging to him as its author, he has a right to sell the use of the same to a patient for his own benefit without thereby invalidating his claim to his original ownership; and that the apothecary by compounding the same acquires no legal property claim in it, except as a matter of record to justify himself in compounding the same, and his right in the prescription is simply that of a custodian, whilst that of the patient pertains only to the individual use of the prescription."

MR. HORATIO PURSLEY of Weston-super-Mare has presented to the hospital authorities of that town a cheque for the sum of £1000.

DR. RUPSTEIN, an assistant in Professor Frerich's clinic in Berlin, has recently died after three weeks' illness from typhoid fever.

THE Metropolitan Board of Works have instituted a new office, viz., that of ice-inspector; whose duty is to examine and certify to the safety of the ice in the parks. The want of such an official has long been felt; and there can be no doubt that indirectly he will be the means of saving the lives of many of those fools who needlessly rush into danger, which wise men would avoid.

IT is, we believe, arranged that Mr. Ray Lankester will succeed to the Chair of Comparative Anatomy and Zoology in University College. The selection is of the happiest omen; Mr. Lankester is not only eminent as a comparative anatomist of the first order, but is inspired with the true spirit of scientific research; and will, we trust, in the career which is thus early opening before him, found a school of ardent students of comparative anatomy in London. The enthusiasm of science is contagious, and we should like to see the infection spread in our London schools.

PUBLIC MORTUARIES.

AT an inquest recently held in Clerkenwell, statements were made which illustrate the necessity, often insisted on by sanitarians, for public mortuaries. The room in which the deceased was found dead was, like the

body itself, dirty in the extreme. The body had to be conveyed for the *post mortem* examination into a lower room, where there was neither table nor chair, nor any other convenience—the place, moreover, being unfit in every respect for the purpose, and so situated that grave danger to the health of the other inmates of the house would have been incurred had the mortal disease been of an infectious character. The Coroner, Dr. Hardwicke, in summing up the facts of the case, remarked on the necessity for a mortuary in the parish, and alluded to the difficulties experienced by the vestry, especially in regard to obtaining a site. While crediting the particular vestry with "trying to do all they can" to supply the admitted want, we confess to have seen the above excuse for delay put forward so often, as to suggest some doubts of the sincerity of those public bodies by which, or in behalf of which, it is made. The real difficulty often, we suspect, is the unwillingness of vestries to incur the expense, and the excuses for delay are ingenious rather than serious. Where there is a will there is a way. If the vestries would vote the money, the site would often be forthcoming—at any rate, it might be obtained. The need of mortuaries is now generally admitted in theory, but we do not expect to see them in general use until the permissive powers contained in the Sanitary Act, 1866, and other enactments, are made compulsory, with additional powers for the acquisition of land. But even then, we fear, mortuaries would be little used unless some arbitrary power of removing the dead, in suitable cases, were lodged in local sanitary officers, thus obviating the delay which now arises in putting the machinery of the law in motion. Apart from the gain to the public from the speedy removal of bodies of those who have died from infectious diseases—all the more necessary on account of our system of delayed interment—the general use of mortuaries would remove a scandal of common occurrence arising from the long detention of the dead in the very midst of the inhabitants of the crowded single apartments in which many thousands of our poorer classes reside. We cordially endorse the sensible remarks of the Coroner in the case above referred to, and trust that the expression of his opinion and that of the jury will stimulate the vestry of Clerkenwell, and other vestries also, to more earnest efforts to supply this great public want.

A TERRIBLE SITUATION.

THERE seems to have been some negligence in the inspection of the ship *Forfarshire*, which left Calcutta for Demerara on the 18th of August last, with 510 Coolies on board. We are told that, previously to leaving Calcutta, the Coolies underwent medical examination; but when the ship had been only two days on the voyage cholera broke out amongst the Coolies, and within the next eight days forty of them were down from the disease. In five days no fewer than thirty deaths took place; and at one time, according to the captain's statement, "It looked as if every soul on board would be attacked". To add to the distress of the situation, measles appeared among the children, five of whom died from this disease, in addition to twenty-two from cholera. The death-list on the passage amounted to fifty-two souls. When the poor creatures died their bodies were wrapped up in blankets and thrown into the sea with as little delay as possible, as the crew "had to give their attention to the living". The suddenness of the outbreak, and the severity of the mortality, points to some evils of overcrowding and to defective sanitary arrangements generally. We are not informed whether the ship carried any surgeon, and find no mention of such an official in the account whence we obtain the above distressing details.

ENTERIC FEVER AND INTERMITTENT WATER-SUPPLIES.

DR. KING has brought under the notice of the sanitary committee of the Town Council of Hull, the circumstances under which, in his opinion, an outbreak of enteric fever prevailed in that borough during the past autumn. In September and October last, five hundred and twenty-six cases of fever were attended by four medical men in Hull; and, since there are between fifty and sixty medical practitioners in the town, it is believed that many other cases than those enumerated must have occurred. The outbreak was to a considerable extent inexplicable, but, when viewed in connection with the experience recently gained in

Lewes, it becomes highly probable it was, in common with the latter outbreak, due to a pollution affecting the water in the mains. Just about the date of the outbreak, Dr. King noticed that the water-supply became very intermittent, and his attention was specially drawn to the continuous stream of air which was forced out of the water-pipes when some of the taps were opened. At times, also, this expelled air had an offensive odour, and some persons have even complained that the water itself, issuing at that time from the mains, had a bad smell. Dr. King states that he has fully satisfied himself that air has, during the intermissions in the water-service, been drawn into the mains; and since the water-mains, in their course through the streets, lie in close proximity to the sewers, there is every reason for believing that foul air, if not other foul matters, has had facilities for entering the water-pipes. Indeed, in Dr. King's opinion, the parallel between the outbreaks at Lewes and in Hull is complete; and he gives it as his opinion that, if the water-supply in Hull had been constant, instead of intermittent, the large amount of enteric fever which has recently prevailed would never have taken place. Some members of the Hull sanitary committee evidently failed to appreciate the dangers associated with the intermittent system of water-service, and, after some discussion, the matter was allowed to drop. That this subject will turn up again, both in Hull and in other places where facilities are afforded for this special form of water-pollution, we have but little doubt; and from communications which we have recently received, we are glad to find that interest is expressed in the experience gained at Caius College and in Lewes, and additional attention is being drawn to the necessity which everywhere exists for a constant system of high pressure water-service.

HYDROPHOBIA.

MR. W. J. PAYNE, the City Coroner, lately held an inquest at St. Bartholomew's Hospital, on the body of John Sweeting, who died from hydrophobia. The deceased had been bitten by a bulldog on the hand last summer. For some time the wound progressed, but recently he had been compelled to go to the hospital. Mr. William Sheard, house-surgeon, deposed, that he received the deceased into the hospital, and all the symptoms of hydrophobia set in, from which he died on Saturday, December 19th. A verdict of accidental death was returned.

THE METROPOLITAN HOSPITAL SUNDAY.

A PUBLIC MEETING, called by the Committee of the Hospital Sunday Fund, was held at the Mansion House on Monday last, at which the Council was reappointed for the year, and the Report of the Committee of Distribution adopted; but, as the supporters of dispensaries and special hospitals are not yet satisfied with the awards they have received, a committee was specially appointed to examine and report upon the claims of these institutions, and generally on the basis upon which the grants ought to be made. It was determined that Sunday, June 13th, be fixed for Hospital Sunday in 1875, and that the co-operation of the clergy and ministers of all denominations be again invited.

BOIL-PEST IN TRIPOLI.

DURING the early part of the present year, a rare and malignant disease made its appearance in a certain district in Tripoli, characterised by the formation of two or three boils in the axilla, or upon the arms, legs, or abdomen. Of ten instances of the affection observed by Dr. Reval, seven terminated fatally within twenty-four hours. It was regarded as a significant feature that the disorder was limited to the members of the tribe of Merdji, the inhabitants of the surrounding districts enjoying an immunity from the malady, although they maintained uninterrupted communication with this tribe. The authorities at Constantinople appointed a commission to inquire into the causes of this epidemic, and this commission, the President of which was the American consul, Mr. Temen, have recently made an exhaustive report. In accordance with this report, the epidemic in question had its origin in miasmata pro-

ceeding from a burial-ground in Merdji, where it is the custom to inter the dead in shallow graves scooped out of the sand, the corpses being simply covered with straw. When it rains, these graves are filled with water, which, upon the following day, is rapidly evaporated by the hot sun, and this contributes to the rapid decomposition of the bodies, by means of which the surrounding atmosphere is loaded with putrid emanations. In winter, the graveyard is converted into a small lake, the water from which is used for drinking purposes. It was also shown that all the wells of the place had their uniform source in this "cemetery pond".

THE LATE SIR J. R. MARTIN.

THE will of the late Sir James Ranald Martin has been proved recently by Sir William Fergusson and George David Pollock, the acting executors, the personal estate being sworn under £35,000. The testator bequeaths to Henrietta Lady Buller, £200 free of duty; to his wife, Dame Jane Maria Paton Martin, certain furniture, to be selected by her, and the income of the residuary estate for life; at her death, he divides his property equally among his three daughters—Miss Ann Macdonald Martin, Miss Julia Errington Martin, and Miss Amy Forbes Martin, with the exception of the articles of plate presented to him by the inhabitants of Calcutta and the medical officers of the Bengal service, which, on the death of his widow, he gives to his son, Simon Nicholson Martin; and, on his decease, to his son, with the intent that they may become heirlooms in the family.

ACTION FOR RECOVERY OF FEES IN A MIDWIFERY CASE.

THE following case, of some interest to the medical profession, has just been decided in the County Court of Liverpool before Mr. Perronet Thompson. Dr. D. W. Parsons, under special circumstances, had agreed to attend the wife of a journeyman printer in her confinement, for the minimum fee of one guinea. The labour proved exceptionally difficult, rendering it necessary to use instruments, and to call in the assistance of a second practitioner (Dr. Parsons's assistant), for the purpose of administering chloroform. For this extra service, Dr. Parsons charged one guinea in addition to the original fee, and half-a-guinea besides, for two additional visits subsequent to the ordinary attendance after labour, thus making his claim £1:11:6 over and above the original guinea fee which had been already paid. The claim was disputed by the defendant, on the ground that, as the original contract was for one guinea, the doctor was bound to do all that might be necessary for his wife's safety for that sum. The plaintiff produced evidence to show that it was understood by the profession, that, in naming the fee for a confinement, especially a minimum fee, it was assumed the case would be an ordinary one, and that, if necessity for further assistance arose, as in the present case, for the administration of chloroform, additional remuneration would be demanded. One of the defendant's witnesses deposed, that a practitioner in large practice in Liverpool, had attended his wife in her confinement, administered chloroform, and stayed with the patient for nine hours, and only charged one guinea. Another medical man, of many years' standing, had also charged a guinea only where chloroform was used. In neither of these instances, however, was there such special difficulty in the case as to require the assistance of a second medical man. The judge gave the plaintiff a verdict for the 10s. 6d. for the extra visits, with costs, but disallowed the £1:11:0 charged for chloroform; expressing his regret that the case had been brought before him at all, and suggesting that it would perhaps be better for those who could not afford the fair remuneration due to practitioners of respectability and repute, to have recourse to parochial or other eleemosynary sources of medical aid. He regretted that, in this case, the strict letter of the law obliged him to rule that Dr. Parsons was bound by his contract, and advised that, in future, medical men should protect themselves in such cases by a previous stipulation, that the fee agreed upon, was not to include exceptional difficulties which might arise. His honour remarked, that a surgeon might agree to cure an ulcer of the leg for a certain sum, but if, in the course of the case, erysipelas or gangrene ensued, render-

ing amputation of the limb necessary, it would be unreasonable to expect the surgeon to bring his instruments and assistants, and cut off the patient's leg, without additional remuneration. Dr. Parsons stated that he had brought the case before the court for the purpose of obtaining a legal decision on the special point, without reference to the question of remuneration in this particular instance.

OBSTETRICAL SOCIETY OF LONDON.

THE following is the house list of officers for 1875. *Honorary President:* Sir Charles Locock, Bart., M.D. *President:* *W. O. Priestley, M.D. *Vice-Presidents:* *W. F. Cleveland, M.D.; E. Copeman, M.D. (Norwich); *T. F. Grimsdale (Liverpool); A. Meadows, M.D.; W. S. Playfair, M.D.; C. H. F. Routh, M.D. *Treasurer:* G. C. P. Murray, M.D. *Honorary Secretaries:* A. Wiltshire, M.D.; A. W. Edis, M.D. *Honorary Librarian:* James H. Aveling, M.D.; *Honorary Members of Council:* H. Oldham, M.D.; R. Barnes, M.D.; J. H. Davis, M.D.; Graily Hewitt, M.D.; J. Braxton Hicks, M.D., F.R.S.; E. J. Tilt, M.D. *Other Members of Council:* G. G. Bantock, M.D.; J. Bassett, M.D. (Birmingham); *W. Bloxam, M.D.; G. B. Brodie, M.D.; T. Chambers, M.R.C.P.Ed.; W. H. Day, M.D.; J. Ellison, M.D. (Windsor); J. H. Galton, M.D.; *W. C. Grigg, M.D.; W. Newman, M.D. (Stamford); J. B. Potter, M.D.; *G. Roper, M.D.; *H. Cooper Rose, M.D.; Heywood Smith, M.D.; A. B. Steele, L.K.Q.P.C.I. (Liverpool); *T. Taylor, F.R.C.S. (Birmingham); *John Williams, M.D.; *J. L. Worship (Sevenoaks). Those gentlemen to whose name an asterisk is prefixed were not on the Council, or did not fill the same office, last year.

THE FEVER AT OVER-DARWEN.

At a meeting of the Darwen Local Board, last week, a statistical table was submitted, prepared by an officer appointed for the purpose, giving information as to the existence of fever. Where the town's water had been used, 1,156 houses, with 6,796 inmates, had been visited with fever. The number of fever cases was 2,035, and the deaths 104, or an average of 1,760 to each house. In eighty-seven houses, with 552 inmates, where water had been obtained from other sources, the number of fever cases had been 126, and the deaths 8, averaging 1,450 to each house. The total number of fever cases had been 2,171, and the deaths 112; or one to every 202 persons. It is stated that the origin of the outbreak has been traced to the contamination of the water-supply of the town by the filtration of typhoid excreta from an imported case into the main water-pipe of the town where it crossed a field on its way to the town, and lay contiguous to a house-drain. So that, during the progress of the first case, the whole town was being steadily poisoned. This is a terrible lesson—like so many others which have arisen and passed away but half learnt—of the deadly effects of impurity of drinking-water.

THE MEMORIAL TO THE COMMITTEE OF COUNCIL.

THE memorial to the Committee of Council on the subject of the hospitals and free dispensaries, which we printed *in extenso* last week, has since then received the following additional signatures: Sir J. Cordy Burrows (Brighton), Dr. Sieveking, Dr. Robert Barnes, Dr. Greenhalgh, Dr. Alexander Halley, Dr. Edward Sparks, Dr. E. Gwynn, Mr. W. Eddowes (Shrewsbury), Dr. John Cook, Dr. W. Center, Dr. Alexander Grant, Mr. J. R. Morrison, Dr. Alfred Pullar, Dr. Waggett, Mr. C. M. Frost, Dr. Mair, Dr. Dow, Mr. J. R. Lynch, Dr. A. D. Walker, Dr. Kilner, Mr. Thomas Liddall, Dr. Howes, Dr. Pearson, Dr. Stewart Tulloch, Mr. H. C. Lawrence, Dr. Hett, Mr. J. M. Moullin, Mr. G. T. Phillips, and Mr. George Beamish.

THE LETTSOMIAN LECTURES.

ON Monday evening last, the lecturer for this year, Mr. Maunder, delivered the first of his lectures to a well attended meeting. The subject, "The Surgery of the Arteries," is one of great interest to surgeons, and Mr. Maunder added to this natural interest the additional one of giving the result of his personal experience, which is exceptionally large. In

addition to the information gained from the twenty-seven arteries Mr. Maunder has tied, he was enabled to give the results of research into various British and foreign journals, and to draw conclusions worthy of attentive consideration from all practical surgeons. The last lecture dealt with the subject of Aneurism; the next will be devoted to Wounds of Vessels.

ROYAL COLLEGE OF PHYSICIANS.

THE lectures of the present year will be delivered at the College, Pall Mall East, on each of the following Wednesdays and Fridays, at five o'clock: Goulstonian Lectures, Dr. R. J. Lee, February 19th, 24th, and 26th, on Puerperal Fever; Croonian Lectures, Dr. Greenhow, March 3rd, 5th, and 10th, on Addison's Disease; Lumleian Lectures, Dr. Beale, March 12th, 17th, and 19th, on Life, and on Vital Action in Health and Disease.

THE PATHOLOGICAL SOCIETY OF LONDON.

ON Tuesday evening, January 5th, this Society met for the purpose of electing a new staff of officers. The retiring president, Sir William Jenner, Bart., occupied the chair. There was a large attendance of Fellows. In vacating the chair, the ex-President expressed, in brief but well-chosen sentences, his gratitude for the vote of thanks proposed to him, and his regret that the multitudinous calls upon his time should have interfered with his attendance. He congratulated the Society upon the value of the specimens exhibited, and the character of the discussions that followed. The Morbid Growths Committee and the new Chemical Committee, called forth expressions of approval from him. Sir William referred especially to the two great discussions on tubercle and on cancer, which had taken place during his presidency. He did not think that the expositions had made converts; for opinion had remained the same. What they had achieved was the bringing out more clearly the discrepancies and disagreements of opinion existing. In setting forth each separate view, much of the other side was seen, and thus each saw more distinctly the differences existing; and from this the truth will ultimately be struck. The proposition to change the hours of the meeting from 8 P.M. to 9.30 P.M., to 8.30 to 10, was carried unanimously. By the liberality of one of the Fellows, Dr. T. B. Peacock, an index of the *Transactions* for the past ten years was furnished to the Fellows. The gentlemen whose names were given in our last issue, as being proposed for election, were unanimously elected. The plan of having special discussions will be followed out, as that on cancer was productive of much interest. Microscopes and illumination are now provided for exhibitors. During the past year eleven Fellows have died, leaving the present number 515. The finances of the Society are in a satisfactory condition.

ON EMBALMING.

THIS is a subject of much interest, and occasionally the members of our profession are called upon, at a moment's notice, to undertake it on the bodies of distinguished persons, as in the case of the late Emperor Napoleon. Only a few weeks since, we received an urgent message by telegram from Southampton, to send down some gentleman learned in the matter, to exercise his skill upon a subject about to be dispatched by one of the West Indian mail steamers. We were unable to succeed; and, as so little is known on the subject, we have great pleasure in publishing the following interesting document from the valuable collection of autographs in the possession of Mr. T. M. Stone of the Royal College of Surgeons. The body was that of the Earl of Moira; the embalment took place at his lordship's house, and the document is drawn up exactly in the following terms, and signed by the late Sir John Dorant, who, on giving it to Mr. Stone, said he was the last surviving pupil of John Hunter.

Modern Embalment by the late Mr. John Hunter.—The whole of the viscera, thoracic and abdominal, having been removed, the entire inside of the trunk was well washed with cold lime-water, and afterwards well dried with cloths. When dry, the cavities were actually soaked in rectified spirits of wine. On the removal of the contents of the abdominal cavity, incisions were made into the intestinal canal, to

give vent to the fecal contents, as also to the gas that might have been contained within them; they were immediately immersed into cold lime-water, well washed, and the blood that appeared well squeezed off. This effected, the whole were again immersed into lime-water, and allowed to remain for a time. This last being finished, the whole was then into rectified spirit of wine, and suffered to remain for some time. The abdominal cavity having been laid as directed, and a bed of spices having been prepared to receive the viscera, the latter was then returned & replaced; the whole cavity, with its contents, was entirely filled with the spices and alum, so as not to leave a vacant space. The abdominal integuments were then closely drawn together, and strongly sewn with twine well waxed. The thoracic viscera were in part treated in the same manner as the abdominal viscera, as also was the cavity of the chest. The lungs having been replaced, and the cavity completely filled with spices, etc.; the integuments closely drawn together and sewn with twine well waxed (the blood was well squeezed from the lungs before immersion, and incisions having been made, Friar's balsam was poured into them). The heart, after having had several incisions made into its substance, was immersed, as before described, in the lime-water and spirit of wine. A considerable quantity of the Friar's balsam was poured into all the openings, and the arteries and veins plugged (off) with the spices, etc., well wetted or soaked in the balsam. The heart was then placed in the urn, well filled with spices, and again soaked with the balsam. The urn was then hermetically closed. The scalp being most carefully removed, the cranium was sawn through so as to remove the upper and larger portion. The brain was carefully removed. The bony cavities were treated in the same manner as the other cavities. The brain was divided into many parts by small incisions or deep punctures, and a considerable quantity of Friar's balsam poured into them. It was carefully replaced within the cranial cavity, well covered with this balsam, so as to envelope the whole mass. The scalp was well drawn over the whole cranium, and closed by being closely sewn with twine well waxed. The mouth and throat were crammed with the spices wetted with the balsam, as also the nostrils. Nothing was done to the lower parts of the body that I remember, neither have I any note as such. The body was well washed with lime-water, and, when perfectly dry, every member was separately rolled in waxed cloth, and afterwards the whole body closely enveloped in the same. I forgot to mention, the bladder was treated in the same manner by the different immersions, and crammed with the spices. The apothecary who supplied all the materials that were necessary by tenure of office, was Mr. Wainwright, who resided in Pall Mall, opposite to Carlton House, within a door or two of St. Alban's Street, as it was at that period. The spices were composed of the more aromatic and pungent order, as cloves, nutmeg, cinnamon, pepper, frankincense (*vis*), etc.; added to which was a large portion of alum in powder. All were reduced to a coarse powder. Performed by Mr. (afterwards Sir) Everard Home, my-ejecting as assistant, and all under the immediate direction of Mr. John Hunter. — (Signed) JOHN DONATT.

The cost is not given; but on reference to Nightingale's *London and Middlesex*, vol. iii, p. 528, we find that Edmund Phillips had £40 4s. 8d. (a large sum in those days) for embalming the body of Thomas Sutton, the benevolent founder of the Charterhouse. The use of the cerecloth, alluded to by Sir John Donatt, has been continued from the earliest to the present period. In the instance of George II. the two sergeant-urgeons had £122 8s. 9d. each for opening and embalming, and the apothecary £152. for a fine double cerecloth and a due quantity of rich perfumed powders.

ACCIDENTS FROM FROST AND SNOW.

ON New Year's evening, there were no fewer than 260 accidents, all more or less of a serious nature, in Paris alone, in consequence of a fall of snow and sleet when the temperature was below freezing. In the provinces, also, the papers report numerous casualties, broken limbs having been of frequent occurrence; and several fatal cases were recorded.

THE ANONYMOUS BENEFICATOR.

THE late Mr. Benjamin Attwood of Cheshunt, whose anonymous donations have for a long time attracted public attention and surprise, has, during his lifetime, distributed not less than £375,000 to various charities. He certainly, during his lifetime, did good by stealth; and it was probably not by his wish that his generosity has become known to fame.

THE FIJI ISLANDS.

A REPORT upon the effect of the climate of Fiji on Europeans and white men generally, has been compiled by Staff-Surgeon Messer, of H.M.S. *Barb*, from information collected in 1873 and 1874. Now that the cession of Fiji to England makes it probable that English subjects will take up their residence in this, our newest possession, the information acquires a practical interest and value. Staff-Surgeon Messer informs us that the climate of the Fiji Islands is strictly tropical, the hot moist season extending from November to April, and the cool dry season from May to October; but strong trade winds and the insular arrangement of the land have a powerful influence in moderating the temperature, and materially check the spread of disease, and prevent the accumulation of poisonous miasmata arising from the enormous quantity of decaying vegetable matter. Zymotic diseases, such as small-pox and fever, are as yet nearly unknown in Fiji; and periodic diseases, such as ague and remittent fever, which owe their origin to malaria, are, strange to say, very rare, if not altogether wanting. The native race is chaste, and venereal disease is at present almost unknown. In no part of the group did Dr. Messer hear of any death from sun-stroke, although most of the Europeans work the whole day in the open air, exposed to a tropical sun, wearing only an ordinary straw hat and puggery, or occasionally a pith helmet. Throughout most of the year, the breeze keeps the air in motion, and produces evaporation from the surface of the body, decreasing its temperature. Asthma and bronchitis, however, are very common among the natives, and, at certain seasons, very fatal to the old and the very young. Of the prevalence of delirium tremens, there is no lack of evidence. The natives maintain that "kava drinking" is useful and healthy. It soothes somewhat like opium, and is a warm aromatic, stomachic drink; but it is evidently hurtful when taken to the extent to which many white people indulge in it. Dr. Messer says: "Dysentery is the only disease which Europeans have to fear in Fiji and to guard against, as can generally be done by observing a few simple precautions. This is saying more for the climate and health of these islands than can be said of almost any other climate or country in the world, and certainly of those in corresponding latitudes." But he notices that, although the climate does not exert any very baneful influence on the European constitution, there yet exists a well-marked difference, distinguishing the Fiji settler from the occasional visitor or the fresh arrival from England. This difference, he says, consists in a spareness of frame, a somewhat sallow complexion, and a hard keenness of expression, approaching sensibly the American type of the Anglo-Saxon race; yet, while fat white men are very rare in Fiji, fat natives are the rule. This is quite in keeping with the effects of most hot climates on the English race. The effect of the climate becomes more evident in women, who have not much out-door exercise, and who are obliged in a rough new country to work hard. Dr. Messer observes that many days occur, especially towards the end of the summer, when, the trade winds failing, there sets in hot, oppressive, muggy weather, affecting many people with an insupportable languor; but he thinks it very doubtful if there is anything peculiarly depressing and lowering in this more than in any other equally hot climate; and the fact that Englishmen, fresh from home, are able to work all day, exposed to the sun, without suffering, shows that where there is an object to be gained, men of determination and energy, with healthy bodies and minds, can successfully contend against this effect of the climate of Fiji. With regard to the possibility of rearing white children in health to the age of maturity in a new country, it requires the test of many years' experience to determine this; but, wherever Dr. Messer met with married settlers among the plantations of Fiji, numerous and healthy children seemed to be the rule, and the mothers bore testimony to the lightness of their children's complaints, and the rarity of any sickness among them. Even though meagreness of frame was remarked among the parents, yet the off-spring were stout, ruddy, and strong. The children on the plantations have a great advantage over those in the town of Levuka; the latter are, in comparison, pale, small, and rather

sickly-looking, owing chiefly to sanitary defects, and the greater scarcity of food suitable to children. Upon the whole, Dr. Messer's report shows very great salubrity in Fiji, considering its position as a tropical country.

THE MAGNETIC FORCE OF BLOOD.

A PAPER was read at the Royal Society on December 10th, by Dr. Shettle of Reading, on the paramagnetic condition of arterial blood as distinguished from the diamagnetic condition of venous blood. The following is an outline of the author's views. This paramagnetic force is due to the presence of oxygen, under the influence of which gas, all the phenomena of animal life are performed. It had been previously ascertained, that the corpuscles of the blood are paramagnetic in both the arterial and venous states; but these experiments by Dr. Shettle prove that paramagnetic force exists in arterial blood which becomes converted into diamagnetic force when the blood passes into unstimulating venous blood. It is true, that the paramagnetic force thus displayed, is small in amount when compared with iron or other paramagnetic bodies of a similar nature, but it is in proportion to the amount of oxygen which the arterial blood contains, for it is a physical property of oxygen. The author of the paper affirms, that in proving arterial blood to possess this force, he proves also, that the stimulating force of arterial blood is due to magnetism, for each atom or molecule of oxygen that is carried into the system by means of the blood, must exercise a paramagnetic—that is, polar influence—over the growing tissues, all of which are known to be diamagnetic to oxygen. In a paper by Dr. Shettle, published in the *Medico-Chirurgical Review* for January 1871, he indicated the mode in which the heart's action would be stimulated if the blood were paramagnetic, and referred the formation of the ganglia of Beale to the action of the same force. In his present paper, he proves the existence of that paramagnetic force by defibrinating blood in the arterial and venous conditions, and then testing them antagonistically to each other. He is now engaged in conducting other experiments with a view to demonstrate that the phenomena of life may be attributed to the molecular action of such force according to the laws of magneto-electricity, or electro-magnetism.

CHLOROFORM AND ETHER.

IN view of the mortality in this country from chloroform, we feel called upon constantly to insist upon a fuller attention to the greater relative safety of ether. "The terrible and indisputable fact is, that no human care, wisdom, or foresight, can prevent occasional deaths from chloroform. On the other hand, only the grossest mismanagement can render ether inhalation fatal." This sentence we extract from the last number of the *American Quarterly Journal of Medical Sciences*. As the American experience of ether is very large, and as this journal is the chief medical authority in the United States, we invite particular attention to this clear and pregnant statement. It would only lose by additional comment.

SCOTLAND.

LEAD IN LEMONADE.

At the Glasgow police-court, on December 26th, a lemonade manufacturer, named James McCasker, was convicted of having sold lemonade that contained four-tenths of a grain of lead to the gallon, and was fined £3 3s., with costs.

THE RECENT COLD WEATHER.

THE effects of the recent severity of the weather has made itself apparent in the death-rates in all parts of the kingdom. In Glasgow alone, the deaths were at the rate of 50 per 1000 *per annum*, the aged and infirm forming, of course, the chief number of the victims. The number of deaths in the eight principal towns of Scotland exceeded the births by 148, and was 340 more than in the corresponding period of last year.

IRELAND.

At a meeting of the Royal Academy of Medicine of Belgium held on the 26th ult., Dr. Redfern, Professor of Anatomy and Physiology in Queen's College, Belfast, was elected an honorary member.

ADDRESS TO MR. A. RINGLAND.

LAST week, the pupils at the Coombe Lying-in Hospital, Dublin, presented this gentleman, who is assistant-master, with an address, expressive of the assistance which they had received from him in pursuing their studies at the hospital.

THE DROGHEDA CORPORATION, AND THE PUBLIC HEALTH ACT.

At a meeting of this body, held last week, a communication was received from the Local Government Board, regretting the views taken by the Council of the Corporation, in giving no salaries to the medical gentlemen on whom devolved the working of the Act, which necessitated their issuing a sealed order, directing that £10 additional should be paid to the salaries of each of the medical officers of the dispensary districts.

UNIVERSITY OF DUBLIN.

THE election for a representative in Parliament for this University is expected to take place about the 13th instant. The electors are the Fellows, Scholars, Masters of Arts, etc.; they do not pay any fee for the privilege, but each voter must have had his name on the books of the University for not less than two months previous to the election. Three candidates have intimated their intention to contest the vacancy, viz., Messrs. Gibson, Miller, and Traill; the last named gentleman is a member of the medical profession, the other two both belong to the legal profession. Mr. Gibson, in his address, promises that, if returned, the interests of the medical profession shall receive his earnest attention; and that he will endeavour to improve the condition of the public services, and advance the progress of sanitary legislation.

THE CITY OF DUBLIN HOSPITAL.

MR. JOLIFFE TUFNELL has been appointed Consulting Surgeon to the City of Dublin Hospital; and Mr. Henry FitzGibbon, son of the well known Master in Chancery, has succeeded to the surgeoncy lately held by Mr. Tufnell. We understand there were five or six candidates in the field, but some retired, believing that the price demanded was above the value of the place. We presume, the highest bidder obtained the appointment; and it is useless, therefore, to discuss the relative merits of the candidates. We believe that arrangements have been made which will gradually result in the abolition of the purchase system at this hospital, and that this is the last occasion where an outgoing officer will be able to sell the right of succession to his office.

NEW MEMBERS IN 1875.

WE are happy to state, that the prospects of the growth of the Association this year are of the most promising kind. Upwards of two hundred members of the profession have already, during the last week, applied direct to this office for admission as members of the Association. We beg to remind the officers of Branches, and the members of the Association generally, that the present is the most desirable season for introducing new members. The officers of certain Branches (the Midland, the Birmingham and Midland Counties, the North of England, Aberdeen, and others) have already applied for copies of the programme of the JOURNAL to assist in a local canvass. It is a very useful and advantageous custom, that the officers of each Branch should systematically canvass their whole district at the commencement of each year. The result is always advantageous to the Branch, and to the whole Association. The total number of new members who have already expressed their desire to join the Association this year is, we believe, greater than in any previous year at so early a date, amounting in all to not fewer than 350. The Association already

numbers more than 6000 members, and the weekly issue of the BRITISH MEDICAL JOURNAL to members and subscribers, has now reached 7000. The friends of the Association will, we trust, not relax their efforts until the total number of members amounts to at least 10,000.

We beg, therefore, earnestly to urge upon the officers of Branches, and members generally, to lend their aid in making known the advantages of the Association in their districts, and thus to hasten the desired consummation. For this purpose, every facility will be afforded on application to the General Secretary, Mr. Francis Fowke, at the office, 36, Great Queen Street, W.C.

WHAT HAS VIVISECTION DONE FOR HUMANITY?

RECENT circumstances render it desirable that some attempt should be made to answer the question whether or not the practice of making experiments on living animals has materially aided the progress of medical science. To answer this question with completeness, would involve an encyclopædic investigation of the sources and history of our present knowledge. It would be a work into which a great fund must be brought of patience, time, and labour. We shall, however, endeavour to present here at once and hastily some leading data, such as may be gathered from a cursory review of the subject. We offer them as *minors fur totum*, and shall hope to be able to finish the picture by filling these rough outlines as time and circumstances will permit. We invite assistance and criticism from physicians, surgeons, and physiologists. We present to-day a first contribution in the following skeleton sketch.

WHAT HAS VIVISECTION DONE FOR MEDICAL SCIENCE?

A. It has succeeded in advancing our knowledge of Physiology, by:

1. Discovery of the two classes of nerves, sensory and motor, by Sir Charles Bell.
2. Discovery of the functions (motor) of the *portio dura* of the seventh pair by Sir Charles Bell. Previously to this discovery, the *portio dura* was often cut by surgeons for the cure of neuralgia!
3. Discovery of the functions of the anterior and posterior roots of the spinal nerves by Sir Charles Bell.
4. Discovery of the functions of the anterior and posterior columns of the spinal cord by Brown-Séquard and others.
5. Discovery of one of the functions of the cerebellum in co-ordinating muscular movements by Flourens and others.
6. Discovery of the functions of the grey matter on the surface of the cerebral hemispheres as connected with sensation and volition by Flourens, Magendie, etc.
7. Discovery of the motor functions of the grey matter covering certain convolutions in the anterior part of the cerebral hemispheres by Hitzig, Fritsch, Ferrier, Gudden, and Nothnagel.
8. Demonstration of the circulation of the blood by Harvey.
9. Measurement of the static force of the heart and discovery of other hydraulic phenomena of the circulation by Stephen Hales, Ludwig, etc.
10. Discovery that atmospheric air is necessary to the maintenance of life, and that, when stupefied by its withdrawal, animals may be resuscitated by readmitting it, by Robert Boyle in 1670.
11. Discovery that atmospheric air by continued breathing becomes vitiated and unfit for respiration, by Boyle.
12. Discovery that the air was not only vitiated but also diminished in volume by the respiration of animals, by Mayow in 1674.
13. Discovery of the relation, as regards respiration, between animal and vegetable life by Priestley in 1722.
14. Great discoveries by Lavoisier on the physiology of respiration from 1775 to 1780; namely, that respiration acts only on the respirable portion of the air, or oxygen, while the remainder, nitrogen, is entirely passive in the process; secondly, that when animals are confined in a limited space, they die when they have absorbed, or converted into carbonic acid, the greater part of the oxygen, and so reduced the air to the state of an irrespirable gas.
15. Numerous facts in the physiology of digestion observed by Blondlot, Schwann, Bernard, Lehmann, and others, by experiments on animals.
16. The discovery of the functions of the lacteals by Colin, Bernard, Ludwig, and others.
17. The discovery of the functions of the eighth pair of nerves in relation to deglutition, phonation, respiration, and cardiac action, by John Reid and others.
18. The discovery of the functions of the sympathetic system of

nerves by Pourfour du Petit in 1727, Dupuy in 1816, Brachet in 1837, John Reid, and Brown-Séquard.

19. The discovery of the phenomena of diastaltic or reflex action by Marshall Hall.
20. The discovery of the action of light on the retina by Homgren, Dewar, and McKendrick.
21. The discovery of the glycogenic function of the liver by Bernard, Macdonnell, Pavy, etc.
22. The discoveries of the whole series of facts in the domain of electro-physiology by Matteucci, Du Bois-Reymond, Pflüger, and many others. These discoveries have important practical bearings.

B. In aiding Medicine and Surgery.

1. The transfusion of blood, and introduction directly into blood of medicines; first proposed by Robert Boyle in 1665. In 1665, Lower transfused blood from vessels of one animal into those of another. First done in human being by Dennis and Emmerets in France in 1666. Blundell's celebrated experiments on animals in 1818. Since done by many others—Dumas, Milne-Edwards, Dieffenbach, Bischoff, Double-day, Brigham, Waller, Burton Brown, Klett, Lane, Lavy, Bérard, etc.
2. Artificial respiration. Vesalius showed that by blowing up the lungs with air, after the chest was opened, stoppage of the heart's action might be delayed for some time. Hook in 1664 first demonstrated the possibility of artificial respiration. Brodie, Hope, Le Gallois, Wilson Philip, Marshall Hall, and Silvester have practised it on human beings.
3. The causes of the cardiac sounds have been determined entirely by vivisectional experiments.
4. Phenomena of the circulation within the cranium examined experimentally by Kelly, Burrows, Reid, etc.
5. Hunter's operation for aneurism was first demonstrated and tried on living animals. This he did in 1785. He also found by experiments on animals that in many cases the arterial coats were diseased immediately above the aneurism, and that consequently it was necessary, in order to avoid secondary hæmorrhage, to place the ligature higher up.
6. The office of the periosteum in regeneration of bone has been demonstrated experimentally by Du Hamel in 1740, Hunter in 1772, Syme in 1837, Wagner in 1853, and Leopold Ollier in 1858. The practical importance of these observations is recognised by all surgeons who have had much to do with diseases of bones and joints.
7. The researches of Kellern into disease of cartilage.
8. The researches of Stricker, Cohnheim, Von Recklinghausen, and many others on inflammation, more especially of cornea and serous membranes.
9. Without vivisection experiments, we would know almost nothing of the phenomena of inflammation.
10. Experimental inquiries into many zymotic diseases showing occurrence of micrococci.

C. In advancing Therapeutics, Relief of Pain, etc.

1. Use of ether.
2. Use of chloroform.
3. Chloral, discovered experimentally by Liebreich.
4. The actions of all remedies are only definitely ascertained by experiments on animals.
5. Action of Calabar bean, by Fraser.
6. Antagonism between active substances and the study of antidotes—many observers.

The above are simply examples which have readily occurred to the mind. To record all the facts given to physiology by experiments on animals, would simply be to write the history of the science. Therapeutics is yet in its infancy; but nearly all the facts definitely known regarding the actions of remedies have been gained by experiments on animals. To stop experiments on animals, would as surely arrest the progress of physiology, pathology, and therapeutics as an edict preventing the chemist from the use of the retort, test-tube, acids, and alkalis would arrest the progress of chemistry.

BEQUESTS.—The late Mrs. Emma Woolsey has bequeathed to the Hospital for Sick Children, Great Ormond Street; the Consumption Hospital, Brompton; St. Mary's Hospital; the National Hospital for the Paralyzed and Epileptic; the Royal Hospital for Incurables, £500 each.—The late Miss Jane Robertson, of Northumberland Street, Edinburgh, has, besides legacies of a private and public nature, made the following bequests for medical charities. To the Blind Asylum, £500; Royal Infirmary, £1200; Deaf and Dumb Institution, £300; Institution for the Relief of Incurables, £100; Convalescent Home, £500; Chalmers' Hospital, £200. The residue of the estate is to be paid two-thirds to the Royal Infirmary, and one-third to the Convalescent Home.

SPECIAL CORRESPONDENCE.

PARIS.

[FROM AN OCCASIONAL CORRESPONDENT.]

Notes in the Hospitals of Paris.

I MADE this week a short visit to some of the hospitals of Paris. It is the vacation season, and I did not see very much; but a short note of what I happened to see may not be uninteresting.

I went round the wards of M. Labbé, in the morning, at the Pitié. M. Labbé is one of the most practical of the hospital surgeons of Paris—active, intelligent, well-read, and a man of the world. He shares, with most French surgeons, the habit of teaching well and clearly: of laying stress upon the particular points on which he wishes to express his views; and of interesting his auditory by vivacity of manner, and by the evident interest which he takes himself in the subject of which he is talking. The habit of *concours*, repeatedly encountered, gives to French teachers this power of speaking clearly, and of arranging with order and system the matter of discourse. I really do not know how many *concours* a professor of the faculty and hospital physician or surgeon has to pass through; but they are at least half-a-dozen, beyond the examinations for his degree. Not to speak of his eight public examinations for his degree, he has a *concours* for the *externat* and for the *internat* of the hospitals; a *concours* for the office of *agrégé* (often two or three); for the office of *maître des hôpitaux*; and for the professorship. These *concours* last for two or three months each: they include long oral dissertations on subjects chosen at the pleasure of the jury throughout the range of medicine; an original study of great length of some doubtful point, on which the candidate must manage to arrive at, and to sustain, his own opinion, which is bound to differ *tant s'il peut* from that of the rest of the world. Altogether, no man can arrive at the office of professor and hospital surgeon without having cultivated to the utmost, not only his powers of memory and of observation, but also the faculty of arranging his knowledge and systematising his ideas, and so drilling his reasoning powers, that he can, at any given moment, bring to bear upon the subject of the moment all his stores of knowledge and his powers of thinking. The system has, of course, many disadvantages; it tends too much to cast all sorts of temperaments and capacities into one iron mould; it aims too much at giving to everyone an encyclopædic character during the first ten years of working life, when it is most desirable that the individuality should be left free to develop itself in all directions. But it has this advantage: it ensures a certain good average of instruction and powers of teaching. It is almost impossible for an absolute nullity, a merely incapable, but patient and perhaps well-to-do, imbecile, to climb the ladder in virtue of having his foot placed on the first rung, and being pushed, in the passage of years, by the accumulative force of those who stand behind him. I need not say to Englishmen that that is an advantage which is sometimes enviable, and not everywhere possessed. The students of Paris do not suffer under the system of mere seniority which prevails in England, the inevitable rise of the most incapable person from the most junior post to that of senior physician and surgeon, professor of surgery, and clinical surgery or clinical medicine, while remaining at or below the level of mediocre instruction and feeble capacity which sometimes suffices to introduce a man into the inner positions of some one of the score of great hospitals and schools in London and the provinces. This is a digression, but it is one which only expresses the reflections into which I have been led very frequently during the last few days, in observing the much higher general average of knowledge and teaching power here, to which the hospitals and schools of Paris undoubtedly owe much of their deserved reputation. There are not here, perhaps, so many strongly marked individualities. It would not perhaps be easy to match here Ferguson, Jenner, Gull, Paget, Henry Thompson, Spencer Wells, Bowman, Liston, Hinton, Lockhart Clarke, Burdon Sanderson, Hughlings Jackson, Brunton, Ferriar, etc. But it would be quite impossible to find among the ranks of the hospital physicians and surgeons of Paris intellects so sluggish and minds so ill-informed as are frequently found engaged in the hospital and school work of London.

Let us return to M. Labbé, with a hope that I may be pardoned for this long excursion, and especially with a prayer for indulgence in expressing these opinions. They are, of course, only those of an indi-

vidual observer; and, even if exaggerated or incorrect, they may be useful in the same degree as they are unpalatable. *Experto crede.* I know pretty well the institutions and the men of both countries. The only novelties which I found in M. Labbé's wards were—1. The free and advantageous use which he makes of the galvano-cautery in certain cases; 2. A new experimental treatment, which he is employing, of large spinal abscesses occupying the dorsal site; and 3. His use of the actual cautery in hospital gangrene and acute diffuse cellular inflammation.

Galvano-cautery.—There were, at the time of my visit, in M. Labbé's wards, a number of cases of extensive multiple fistula of the sinuses—examples of these cases in which the disease has lasted for many years. If the sinuses have burrowed in several directions, spreading widely and deeply beneath the glutei, covered by a considerable thickness of tissue, often of a highly vascular character—in such cases, the incisions must extend far and widely; and, from the extent of surface laid open, and the amount of bleeding, such operations often require a good deal of judicious determination and courage on the part of the surgeon, and are a severe trial to the patient. Here M. Labbé had used the galvanic cautery with very good results indeed. The application is not, of course, new, but it is useful. He has used it also successfully in ablation of portions of the tongue, and of polypi, etc. He is careful to heat the wire only very moderately, and to proceed very slowly. By heating the wire too high, others have met with serious subsequent hæmorrhages. This is indeed the frequent objection to the galvano-cautery. It may be avoided, as the experience of M. Labbé and others shows, by using the wire only at a very dull heat, and proceeding with great deliberation; thus, a section of the tongue may occupy twenty minutes, but then there is no subsequent tying of arteries. M. Labbé's experience of epithelial cancer of the tongue is not more favourable as to final result than that of other surgeons.

I may mention here that I saw also, at the *Maison Municipale de Santé*, two cases of M. Demarquay, in which he had tied the lingual artery in order to arrest the growth of a lingual epithelioma, but, of course, without the expectation of doing more than produce a temporary atrophy. M. Demarquay has employed this surgical expedient a great many times; and, in a subsequent note, I will acquaint you with the details of his results, of which he is preparing notes for me.

Abscesses of the Spine treated by Cauteries.—Of these cases, I can have but little just now to say, but you will probably hear more of them, either from me, or from M. Labbé himself, who may probably make you a communication on the subject, either in writing or at your Edinburgh meeting. The treatment of those enormous collections of matter which are found in the course of dorsal spinal disease, where a huge cold abscess forms which has a vast extent of pyogenic surface, is at this moment almost negative. What can be done with these huge spinal abscesses of the back? Open them by Lister's process and inject them, perhaps. We lack, at present, the elements of appreciating the success of this mode of treatment. M. Labbé has been induced tentatively to attempt the plan of destroying the tissues over the abscess for a large extent, and gradually applying chloride of zinc paste, laying bare the whole cavity of the abscess, nonroofing it, so to speak, and converting it into an open granulating wound, to be treated then according to the rules of art. Will this treatment succeed or not? Has it considerable inherent dangers? I cannot tell you. It is an experimental proceeding. The wounds are certainly large, but they looked healthy, as wounds so produced usually do: the patients had, during the course of a treatment which is necessarily long, and which has the appearance of being severe, suffered little, and shown very little febrile reaction. The temperature had hardly, at any time, exceeded the normal by one or two degrees. The patients whom I saw had on their backs open granulating healthy-looking wounds of the extent of the palm of a large hand. Many pints of matter had escaped from one, but the cavity of the abscess was not yet fully exposed.

Of the *actual cautery* in cases of hospital gangrene and diffuse cellular inflammation, M. Labbé speaks with due enthusiasm. I have not seen him apply it in these cases, but he mentioned the particulars of a case of inflammation of the bursa of the olecranon due to a blow. The bursa filled with matter was opened, the case made a good recovery, the wound had nearly cicatrised, and the physical condition of the patient was entirely reassuring. The morning consultation left the patient in this condition. At night, the surgeon was again summoned, the patient having meantime undergone a rapid change for the worse: the arm was swollen to a great thickness from the wrist to the shoulder, a great swelling projected from the elbow, the pulse could not be counted, the patient was in violent delirium. Long deep incisions, followed by the actual cautery to the depth of the incisions, produced a modification as rapid as that which had led to the unfavourable condition, and the patient, who seemed on the brink of death, was restored very quickly

to a sound condition. M. Labbé mentioned several other cases in which the most excellent results had rapidly followed the application of the actual cautery to the flaps of amputation-wounds, and other examples of hospital gangrene. There is not the same fear here of actual cautery as in London hospitals; and I incline to think that its full value is not sufficiently appreciated by the London surgeons.

Paris, December 24th, 1874.

EDINBURGH.

[FROM OUR OWN CORRESPONDENT.]

The Cold Weather and the Death-rate.—Death of Dr. W. Dumbreck.—Hospital Sunday.—University Examiners.—Election of Managers of the Infirmary.—The Lady Question.

THE death-rate for the past week has reached the very high figure of 38 per 1,000, and this fact might well give rise to serious alarm in the face of the recent epidemic of scarlet fever, which has been prevalent in the town, were it not that, on looking into the causes of death, we find only two put down to fever of any kind, while the great rise is due to heart and chest-diseases and "old age". There is no doubt that the very great fall of temperature which has been experienced here in the last week or two has carried off large numbers of the aged inhabitants, whilst among children its effects have been nearly as severe. Here, at all events, we are paying a high penalty for the pleasures of an "old-fashioned" winter, for in none of the severest epidemics of fever and small-pox has so high a mortality been registered in Edinburgh.

We are sorry to record the death of Dr. W. Dumbreck, one of the oldest members of the medical profession here. Till within a few weeks of his death, which occurred at the age of 74, he was engaged in practice, and was in the enjoyment of very fair health. He caught a severe cold about a month ago while engaged in professional work, from which he never rallied. Dr. Dumbreck was a native of Edinburgh, and was for thirty years an examiner in the Royal College of Surgeons, which office he resigned on being appointed, a few years ago, one of the Examiners in Medicine in connection with the University. He long enjoyed a very considerable practice.

The amount received in aid of the Infirmary from the various churches, the result of the collections on Hospital Sunday, is stated to be about £1,550. It is to be noted that, while two of the episcopal churches head the list with £157 and £126 respectively, the highest figure of any of the Presbyterian churches is £77, none of the others—either Established, Free, or United Presbyterian—showing a larger amount than £50. This is a somewhat singular result in a Presbyterian country, and shows either that the wealthier classes mostly belong to the alien church, or that the methods of collection make a vast difference in the amount collected.

The first election of examiners to the University is to take place at the end of this month, and already we hear of several local candidates mentioned for the various subjects, any of whom would do the work satisfactorily; and of course it is to be expected that a good many strangers will put themselves in nomination also. One marked feature in the method of application is, that no testimonials to proficiency are to be sent in by any of the local candidates, and not more than four by anyone from a distance. This is really a good step in a right direction.

There was a general meeting of the Infirmary contributors on Monday afternoon, for the purpose of electing the six managers, whom they have the right of appointing. An unusual amount of interest is connected with this meeting, as for the past few weeks an agitation has been on foot for the purpose of promoting the election of two ladies to fill two of the vacant seats at the Board. The ostensible reason given was, "that the services of ladies on the Board of Management would be of the utmost value, both with regard to the care and comfort of the sick poor, and to the domestic arrangements of the institution". It is curious that the institution has managed to exist and carry on its work with a very high degree of efficiency hitherto, and that, so far as can be made out, no charge of want of care of the patients, or of anything faulty in the domestic arrangements, has been made to justify the desired change in the constitution of the Board. Of course, an opposition list was proposed, in which the lady element was omitted. On the vote being taken on the proposal "to take two ladies on the Management", there was found to be a large majority against the motion, and six gentlemen were accordingly elected. The friends of the ladies protested; on what grounds, or with what effect, is not quite clear.

We had hoped that, after several serious battles, the lady question was set at rest by the migration of the lady students in a body to London; but it really looks rather as if the endeavour to put ladies on to the management of the Infirmary were a strategic flank movement in case the question of the female medical student should again crop up.

ASSOCIATION INTELLIGENCE.

COMMITTEE OF COUNCIL.

NOTICE OF MEETING.

A MEETING of the Committee of Council will be held at the Office of the Association, 36, Great Queen Street, London, on Thursday, the 14th day of January next, at Two o'clock in the afternoon.

FRANCIS FOWKE,
General Secretary.

36, Great Queen Street, London, December 23rd, 1874.

BATH AND BRISTOL BRANCH.

THE third ordinary meeting of this Branch will be held at the Royal Hotel, College Green, Bristol, on Thursday, January 14th, at 7.30 P.M.; FREDERICK MASON, Esq., President, in the Chair.

E. C. BOARD, *Honorary Secretary.*

Clifton, December 29th, 1874.

BIRMINGHAM AND MIDLAND COUNTIES BRANCH: MICROSCOPICAL SECTION.

A MEETING of the above Section was held in Queen's College, Birmingham, on December 11th; Mr. F. E. MANBY, President, in the Chair.

Phthical Sputa.—Dr. SAWYER read a paper on this subject, and on the method and value of a microscopical examination; exhibiting samples under the microscope. A paper on the examination of phthical sputum appeared in the *Lancet* in 1868, and the method of procedure therein advised Dr. Sawyer had often found in practice to be most satisfactory. If we compress a portion of phthical sputum on a slide, we can readily see, with a quarter-inch power, young and old cells, mucus- and pus-corpuscles, blood-discs, "exudation-corpuscles", etc.; but such a plan will not readily show minute portions of pulmonary tissue, and these are the characteristic marks of the destruction of lung-tissue. Following Dr. Fenwick, he had found it best to slowly boil about two drachms of the sputum to be examined in a test-tube, with an equal quantity of solution of caustic soda, which destroys the ropiness. Mucus- and pus-corpuscles are disintegrated; while fragments of less easily destroyed tissue, as minute portions of lung-tissue, fall to the bottom of the tube, and may be removed by a pipette, and placed on a slide for microscopical examination. We may find beautifully slender and curling fibrils of the yellow elastic tissue, or scraps of the smallest bronchial tubes, or shreds of the outlines of groups of air-cells. These are very attractive microscopic objects. In the field, at once may be seen the outlines of half a dozen groups of air-cells clearly marked, with traces of red blood-cells, and scattered portions of coal, or other hard and black insoluble matter. In cases of any doubt, the discovery of fragments of pulmonary tissue in the expectoration will furnish interesting confirmatory evidence of the condition of the patient.

Sections through Small-pox Pustules.—Dr. RICKARDS showed various sections, vertical and horizontal, of these pustules; and described the appearances presented.

Epithelial Cancer of Eyelid.—Mr. LLOYD OWEN contributed sections illustrative of a case of this disease under his care, the tumour having been removed by operation.

Sections of Spinal Cord.—Mr. PHILIP BINDLEY exhibited some sections of a healthy spinal cord. After the sections had been tinted with carmine, they were washed in spirit until all water was removed, and were then placed in turpentine for five or six days, and afterwards mounted in balsam. The axis-cylinders, nerve-cells and their processes, and the blood-vessels with the nuclei, were all well displayed.

Cystine.—Mr. F. E. MANBY showed a slide of cystine from a specimen of urine passed that morning by a lad of twelve years. The patient had passed a small waxy-looking cystine calculus, when only twelve months old, *per urethram*. This was about the size and shape of a grain of wheat. At ten years old, he showed symptoms of vesical calculus, and a cystine stone of a most perfect and typical character was removed by lateral operation by Mr. Newnham. This stone weighed ninety grains. Since the operation, symptoms of stone in the right kidney had developed themselves. The bladder having been proved to be free from a second calculus, it was probable that a stone existed in

* This was announced as 3 o'clock, in error, in the notice of the 26th ultimo and 2nd instant.

the pelvis of the right kidney. Pus and cystine were constantly passed in the urine; and attacks of pain, though not frequent, were severe. There was no hereditary history of stone. The family are of a distinctly neurotic type.

Staining Animal Tissues.—Mr. LAWSON TAIT, at a previous meeting, detailed and illustrated his improved process of staining by means of hæmatoxylin. He also showed a mounted preparation of the scolex of *tænia luapicollis* removed from the broad ligament of a heifer.

BIRMINGHAM AND MIDLAND COUNTIES BRANCH: ORDINARY MEETING.

THE third ordinary meeting of the session was held at the Midland Institute on December 10th, 1874; present, W. C. GARMAN, Esq., President, in the Chair, and thirty-seven members and visitors.

New Members.—The following members of the Association were elected members of the Branch: Mr. Richard Smith, Digbeth; and Messrs. F. G. Hamilton and E. Potts, Queen's Hospital, Birmingham.

Branch Council.—Mr. J. Yose Solomon and Mr. T. H. Bartlett were elected members of the Council of the Branch.

Subscriptions to Branch and Sections.—After some discussion, a motion to raise the Branch subscription to 5s. *per annum*, and to make this sum confer on all members of the Branch the privileges of membership of the Sections, was rejected, and it was resolved, "That the subscription to the Parent Association and Branch remain as at present (£1 : 3 : 6), and that a subscription of £1 : 6 admit to the Association, the Branch, and all its Sections."

Alteration of Rules of Branch.—It was resolved, on the motion of Mr. HUGH KER (Cradley), seconded by Mr. H. L. BROWNE (West Bromwich), "That in Rule 9, line 7, the words "at least a week previously" be altered to "at least two weeks previously"; and that the Council be requested to prepare a copy of the Rules of the Branch for circulation among the members."

The next Ordinary Meeting of the Branch was arranged to be held on January 21st, instead of January 14th, the regular day, in consequence of the closure of the Midland Institute.

Papers.—The following papers were read.

1. Dr. RICKARDS showed the remains of a *Hæmorrhagic Clot* of the size of a horse-bean, fawn-coloured, eleven months old, situated in the outer margin of the right corpus striatum. The patient from whom it was taken, a woman aged 25, had had rheumatic fever with severe cardiac complications thirteen months before her death a few days ago. During convalescence, complete left hemiplegia suddenly came on; the facial paralysis disappeared in two days; the limbs remained paralysed. She died of pulmonary engorgement, caused by stenosis of the mitral valve, which was such as not to permit a crow-quill to pass through that valve. Dr. Rickards considered the cerebral hæmorrhage due to embolism. Under the microscope, the clot was seen to consist of blood-crystals, blood-pigment, cholesterine, and fibrous tissue.

2. Mr. SAMPSON GAMGEE read a paper entitled *Historical and Clinical Notes on the Past, Present, and Future of Surgical Practice.*

SOUTH-EASTERN BRANCH: EAST AND WEST SUSSEX DISTRICTS.

A CONJOINT meeting of the above districts was held at the Royal Pavilion, Brighton, on Friday, November 20th; Sir J. CORDY BURROWS in the chair. Twenty-six members and two visitors were present. In the course of his opening remarks, the Chairman said he felt he ought to bring one subject before the meeting in such a way that the public should know of it, and even that the Committee of Council of the Association should be led to take some steps to remedy the present state of things; viz., the inadequate remuneration which the members of the profession receive for their services to the public. Sir Cordy showed that, although the necessities of life have largely increased in cost, there has been hitherto no commensurate increase in the scale of medical fees, though there has been an increase in salaries, wages, and remuneration in almost all other professions and trades.

Communications.—1. *Treatment of Neuroses by Phosphorus.*—Mr. T. F. SANGER of Alfriston made some practical remarks on the treatment of neuroses by phosphorus, which he had been induced to try through an article in the *JOURNAL* in October 1872 by Mr. Messenger Bradley of Manchester. The preparations which Mr. Sanger used were the ethereal solution (4 grains in 100), and the alcoholic solution (1 in 100); the dose of the former being two to four drops; of the latter, five to ten drops. He had given it with invariable relief in forty

or fifty cases of neuralgia, excepting those proceeding from hepatic congestion, which he found speedily cured by half a drop of croton oil with five grains of compound rhubarb pill. His success with the remedy in neuralgia induced him to try it in other diseases which owed their origin to want of nerve-power, proceeding from innutrition of the nerve; and he detailed the particulars of four cases, by way of illustration, in which cure or signal benefit had resulted; viz.: 1. A case of paralysis agitans, in a woman aged 45, where the disease had existed four years, and was cured in two months; 2. A case of paraplegia after diabetes and sunstroke, in a man aged 46, where recovery was nearly perfect in four months; 3. A case of a widow aged 83, suffering from neuralgia of the sciatic nerve, with severe nocturnal exacerbations, which had been entirely unrelieved by morphia, and only temporarily alleviated by chloral, but was cured by the phosphorus in ten days; 4. A case of a female aged 40, with paraplegia of four years' standing, in whom considerable restoration of motor power followed treatment for two months by phosphorus, in combination with small doses of tincture of perchloride of iron.

2. *Tumour of the Thyroid Gland.*—Mr. H. R. TICEHURST of St. Leonard's read particulars of a case of tumour of the thyroid gland, which he had removed by means of the galvanic cautery. The specimen, which weighed 25½ ounces, was exhibited. The patient was a female aged 46, a servant. The tumour was first noticed twenty-two years ago, being then of the size of a pea, one inch and a half to the left of the thyroid; it increased rapidly towards the middle line, and soon covered the entire region of the thyroid; but had not grown much for the last three years. Two years ago, it was tapped, and injected with iodine; only blood escaped. Its form and size were those of a small melon; it was perfectly movable and pendulous; not pulsatile. On November 4th, Mr. Ticehurst proceeded to remove it, the patient being well under the influence of chloroform. A vertical incision was made over the tumour in the mesial line, and the growth was separated as far round as possible by the handle of the knife; both sterno-thyroid muscles were found flattened out over the tumour. The growth was then removed by the galvanic cautery. No hæmorrhage occurred. The pedicle was found to be osseous, the greater part being left behind. The patient bore the operation well. Severe constitutional disturbance ensued on the following day; this, however, soon subsided, and, with the only drawback of an abscess forming on the right side of the neck, healing progressed satisfactorily, and by December 1st the patient was sitting up, the bony pedicle becoming congested, only a small portion having suppurated away. The tumour was smooth and globular, yellowish in colour, and covered with a thick capsule of connective tissue. It was semi-solid, and weighed 25½ ounces avoirdupois; some large veins ramified over the surface, and on the anterior aspect was a small opening, through which it had been punctured and injected. On making a section of the growth, a kidney-shaped cavity was found about its centre, lined with a distinct membrane of its own; it contained some bluish green fluid and *débris*, probably the remains of iodine, etc. Near the surface, some blood-cysts were found. The rest of the tumour was semi-solid, and contained several small cysts scattered through the spongy portion. Under the microscope, the growth appeared to consist of fibrillated trabeculae of varying size and shape, filled with a colloidal substance, such as is found in hypertrophied thyroid gland, interspersed with cells resembling granulation corpuscles. A somewhat similar growth was removed by the late Mr. Alfred Poland in 1871, the tumour weighing 15 ounces (*Guy's Hospital Reports*, 1870-71). There is also a case of the same kind recorded in Sir James Paget's *Lectures on Surgical Pathology*. The points of interest about this case were—1. The large size of the growth; 2. The duration (twenty-two years); 3. The perfect freedom from hæmorrhage insured by the use of the electric cautery, the dread of which would otherwise have deterred the operator from attempting the removal of so large a growth, occupying important relations with surrounding parts, and abundantly supplied with blood from the enlarged thyroid vessels.

3. Mr. MILLIKIN, instrument-maker to St. Thomas's Hospital, exhibited a new and choice collection of instruments, such as had been recently shown at the Association meeting at Norwich, with several additions.

Two new members were nominated; viz., Mr. E. S. Medcalf of Hove and Mr. Charles Braid of Hurstpierpoint.

The Dinner took place in the Banqueting Room of the Pavilion, upwards of thirty members and visitors being present, including Sir Edward Creasy, the Colonel of the Scots Greys, etc.

By the kindness of the Directors, the Aquarium was thrown open to members of the Association on presenting their cards. A vote of thanks was duly recorded at the meeting to the Town Council for granting the use of the rooms at the Pavilion on this occasion, and also to the Directors of the Aquarium for the above act of courtesy. Sir J. C. and Lady Burrows subsequently entertained the members of the

Association and their ladies at a *concertation* held at the Museum and Public Library.

The next meeting is to be held at Tunbridge Wells in March 1875; Blackall Marsack, Esq., in the chair.

MIDLAND BRANCH: SPECIAL MEETING.

A SPECIAL general meeting of this Branch was held in the boardroom of the County Hospital at Lincoln on December 18th.

The following members were elected on the Council of the Branch, according to No. 8 of the rules lately adopted:—Dr. A. Mercer Adam (Boston); Dr. Mitchinson (Lincoln); Dr. C. H. Marriott, Dr. John Barclay (Leicester); Dr. W. Tindall Robertson, Dr. C. Bell Taylor (Nottingham); Dr. Ogle, Dr. Webb (Derby).—Dr. C. Harrison (Lincoln) was elected Honorary Secretary and Treasurer of the Branch. Dr. L. W. Marshall was elected Honorary Secretary for Nottingham, and Dr. W. Edgar Buck for Leicester.

Members of the Association wishing to join the Branch are requested to communicate at once with the Honorary Secretary and Treasurer.

SOUTH-EASTERN BRANCH: EAST SURREY DISTRICT.

A MEETING was held on December 10th, at the Greyhound Hotel, Croydon, at 4 P.M.; H. T. LANCHESTER, M.D., in the Chair. Fifteen members and two visitors were present.

Papers, &c.—1. Dr. WALTERS read the particulars of a case of Poisoning by Arsenic (ten grains); also a case of Poisoning by Hydrocyanic Acid, in which there were no convulsions. In neither case was *post mortem* examination ordered by the coroner. He also described the removal of a large Naso-pharyngeal Polypus (exhibited) by passing two fingers into the mouth behind the soft palate, and tearing the attachment of the growth by forceps passed along the floor of the nares.—A discussion ensued, in which Messrs. E. H. Galton, Dr. Lanchester, Dr. Grabham, Messrs. Stilwell and Purvis, Dr. Moxon, Dr. Hott, and Dr. Miller, took part.—In the course of the discussion, Dr. Grabham described the symptoms of arsenical poisoning in one hundred and fifty cases at Bradford, from accidental admixture in peppermint lozenges. They were various; deep sleep, skin-eruptions, and paraplegia, occurring in different cases. Dr. Purvis also read a case of poisoning by cyanide of potassium.

2. Dr. MOXON read a paper on Paralytic Tremor as a Symptom. He described tremor or trembling as the opposite of spasm. In detailing the different forms, he mentioned one which appeared to be due to involuntary muscular discharges without nervous stimulus, as in the fibrillar trembling of wasting muscles. Allied to this are the tremors of fevers and violent emotion. He alluded to the difficulty of distinguishing between alcoholic paralysis and progressive muscular atrophy. In tremors, both alcoholic and febrile, we recognise a peculiar nervous constitution in those subject to them, and this leads up to spontaneous paralytic tremor. He then described a group of symptoms associated with a peculiar change in the white matter of the brain, called "insular sclerosis," or "*scleroses en plaques*." In this disease, there is tremor without affection of the mind or true paralysis. The tremor ceases when the part is supported, in this differing from paralysis agitans. The nodding of the head is very distinct. There is stiffness of the legs and absence of pains in the legs; in this it differs from locomotor ataxy. The disease would appear to be not uncommon, as there have been five cases in Guy's Hospital this last year. It seems to be invariably fatal. One case, in a girl aged 23, came on after a shock of horror three years before. The arms and legs oscillated on attempting to sit up; speech was syllabic; nystagmus and mental feebleness supervened. A drawing of the brain in section of this case was shown, representing insular grey patches scattered through the white matter. On microscopical examination, these patches showed no trace of nervous matter. Another case also appeared to originate in shock, the woman finding her husband in bed with another woman. In another case, the first noticed symptom was inability to wipe the shoes.—A discussion followed, in which Messrs. E. H. Galton, Stilwell, Dr. Lanchester, Dr. Miller, Dr. Hott, and Dr. Galton, took part.

3. Mr. STILLWELL (Epsom) read a case of a woman aged 43, in labour with her first child, who died, after delivery and injection of perchloride of iron, of sudden collapse.—Drs. Strong, Hearnden, and Lanchester, made remarks on the case.

4. Dr. MILLER exhibited a left Kidney of normal shape, which was found single in the body; also a Fibroid Growth behind the uterus, freely movable independently of the uterus.

5. Dr. HOTT read Clinical Cases, and exhibited numerous specimens from the Croydon Hospital. Among the cases was one of fracture of

the cervical spine, with a temperature of 111 deg.; one of strangulated hernia, cured in the night by the patient standing on his head; and one of temporary aphasia following injury to the left side of the head. He also read some cases illustrating the use of the Aspirator.

Dinner.—Fourteen members and one visitor sat down to dinner.

REPORTS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, DECEMBER 15TH, 1874.

C. J. HARE, M.D., in the Chair.

The Report of the Morbid Growths Committee on Dr. CRISP's case of cancer of the omentum was read. Microscopical examination showed a fibrous stroma, in which were round and oval alveoli full of cells, each containing one nucleus, while others contained a colloid material. In order to determine whether or not the growth was a true cancer of the omentum, the growing edges were examined very carefully, and yellow fibres were found passing into the alveoli. The growth was due to cells accumulating in the alveoli. The yellow fibres contained round cells. The growth sprang from the epithelium of the omentum. From the length of time the preparation had been kept in spirit, it was impossible to be very confident about its histology.

Rare Form of Skin-Disease.—Dr. DUFFIN exhibited a patient with a rare form of skin-eruption, intermediate betwixt erythema multiforme and herpes iris. The patient was twenty-two years of age, and had suffered for two years from irregular outbreaks, which remained in the same localities. Itching and slight rigors, together with febrile symptoms, preceded the eruption. It commenced with circular flat spots, and spread outwardly, while the centres settled down. The raised patches possessed vessels, and fluid was effused. A secondary eruption formed in time within the first, so that the appearance presented is that of a ring within a ring. Each eruption lasted three or four weeks, but they followed each other so closely as to be almost continuous. Ultimately, brown scabs formed, but there was never any suppuration. It resembled erythema multiforme in the circinate character of the rash and in the bruised appearance, while rheumatic pains were absent. It approached herpes iris in its rings within rings.—Dr. HILTON FAGGE said that the absence of rheumatism went against its being erythema multiforme. Such eruptions were covered by the term hydroa.—The CHAIRMAN remarked that dermatological terms were much confused.—Dr. DUFFIN replied that Dr. Fagge's remarks were well worthy of consideration.

Obscure Abdominal Tumour.—Dr. DICKINSON brought forward a case of an obscure abdominal tumour, in which the obscurity was the especial matter of interest. It occurred in a gentleman well known in the political world, who died recently at the age of 76, after having been seen by many prominent members of the profession. He first felt ill in January 1872, and had swelling and redness in the left testicle, with pain. Then followed pain in the region of the left ureter. At first, the pain was dull and heavy, but in time it became agonising. Change of attitude gave no relief. Pain was felt in the lower bowel. This went on for several months, and then set in constipation and vomiting. The pain was worst when the bowels moved. When Dr. Dickinson first saw the patient, he was apparently in *extremis*, and had several bed-sores. At that time, the abdomen was soft everywhere, and not tender on gentle pressure. Deep pressure, however, to the left of the umbilicus produced severe pain. The diagnosis formed, then, was, that there was a tumour in the descending colon, involving the left kidney and ureter, probably malignant in its character, from the cachectic appearance of the patient. There were no symptoms pointing to renal calculus. Shortly after this, the pain abated, and the patient improved in every way. It was thought that this might be due to the tumour becoming somewhat released, or that the diagnosis might be erroneous, and that the tumour was really aneurismal. Fifteen months after this, the patient's general health failed. A pulsation could now be felt, and became definite at the point where the pain was originally felt. There was no pain or inconvenience. The general improvement came on with the administration of strychnia, as a tonic merely. One day at dinner, the patient changed countenance, and the old look of pain returned. He became unconscious and fainted, but, after some brandy, he was taken upstairs. Two days afterwards, he passed a quantity of black blood from the bowels. He partially recovered by means of quiet, and a week after, at dinner again, he gave a cry and fell dead. At the necropsy, an aneurismal tumour, springing from the left side of the aorta, and protruding betwixt the descending colon and the left ureter, was found. This explained the symptoms. It was of the size of the

fist, and opened into the descending colon.—The CHAIRMAN said that this case illustrated well the difficulty of diagnosing abdominal aneurisms in their early stages. The tumour must have existed when the first symptoms came on, but it did not give the characteristic symptoms of an aneurism.—Dr. CAYLEY inquired as to the cause of the cessation of the pain. Were the nerves atrophied by the pressure on them?—Mr. HULKE said that it had been observed that, when aneurisms burst in a mucous surface, the hole was small: when into a serous surface, the hole was large.—Dr. SOUTHEY inquired if the left lumbar region had been carefully auscultated in life. A thrill and a murmur were not unfrequently so heard; and in one case he remembered they were heard where the case was supposed to be one of lumbar abscess and rheumatism, and consequently the diagnosis of an aneurism was made.—Dr. DICKINSON replied that the pain obviously diminished on the pulsation becoming apparent. No thrill could be found anywhere by the most careful examination.

Cancer of the Tongue.—Mr. JONATHAN HUTCHINSON exhibited a specimen of cancer of the tongue. The interest lay in the fact of there being two separate growths. There was a small patch on the left side, and another about an inch away on the right side. There had been frequent ulceration in the tongue, with white patches. There was an obscure history of syphilis. The microscopical examination bore out the diagnosis. The glands on the right side were now affected. Two centres of cancer were rare. In answer to questions of the Chairman, Mr. Hutchinson said there was no apparent cause. The patient was in robust health. There was a family history of carcinoma. They grew from the edge of the tongue.—Mr. FAIRLIE CLARKE asked if scars were found on the tongue.—Mr. HUTCHINSON said that they were. There were also white patches. The patient was in good general health, but the cervical glands on the right side were affected.

Intussusception in a Dog.—Mr. HUTCHINSON showed a case of intussusception of the ileum into the colon in a dog. The case bore on the question of operation for intussusception. The volvulus extended nearly to the anus. The dog was observed to be ill eight days before its death, but there was nothing special in the symptoms. There was no sickness. The abdomen was much shrunken, and there was jaundice before death. If an operation had been performed, nothing would have been easier than to pull out the whole volvulus. There was no peritonitis nor lymph.—Dr. HILTON FAGGE said that he had seen two operations where the involved bowel was pulled out. In one case of obscure tumour of the abdomen, pain came on with the examination, and the tumour became hard. The diagnosis was intussusception. The tumour had passed from the right to the left iliac fossa. Inflation was unsuccessful. An operation was performed, and the intussuscepted bowel was pulled out. The patient made a good recovery. The second was in Guy's Hospital. The patient was far gone when the operation was performed, and sank of collapse shortly after. In the second case, there were no special symptoms, but only spasmodic pains.—The CHAIRMAN related a case where it was found impossible to reduce the bowel at the *post mortem* examination. This contrasted with the cases just related.—Dr. GOODHART related a case similar to the one mentioned by the Chairman. No traction would reduce the mass, as the folds of peritoneum were glued together with lymph.—Dr. LEARED spoke of a case caused by effort where, after death, the bowel was readily pulled out.—Dr. DOUGLAS POWELL remarked that peritonitis was not readily produced in a dog.—Mr. HUTCHINSON replied that this was quite correct.

Aneurism of the Heart.—Dr. SOUTHEY showed an aneurism of the heart of unusual size. The patient—an old soldier—came under notice two years ago. He had felt something give way on an effort, and after that he felt tightness in his chest and dyspnoea. The area of cardiac dulness was increased, and the heart's action was disturbed by movement. A murmur was heard at the apex, loudest betwixt the fourth and fifth ribs. There were general distress, orthopnoea, and cough. The temperature was 99, the respirations 40, and the pulse 120. The man was much improved by rest and digitalis, and was discharged from hospital. He became a carman, and was fairly well for two years. On October 19th this year, he again came into hospital with left-side pleurisy. A systolic murmur was heard at the apex: it was thought that it might indicate mitral incompetency. The patient was worn and wasted, and had cough, with cedema. The chest was explored by Mr. Thomas Smith: a quantity of pleuritic fluid came away, giving much relief. Pneumothorax, however, resulted, and the man sank. The diagnosis was never very clear. There was a very small hole into the left ventricle. In this it agreed with Thurnam's cases and conclusions, that large cardiac aneurisms had small openings. The aneurism was of the size of a large cocoa-nut. It was globular, and consisted of two divisions united. Large masses of clot were turned out. The left ventricle was not hypertrophied, but rather

dilated. The valves were free from disease. The aorta was atheromatous. The liver was fibrous. There were cedema of the trunk and legs, and effusion into the left pleural cavity.—The CHAIRMAN said that, when aneurisms were near the apex, the sac was largely composed of pericardium.—Dr. WICKHAM LEGG said this was a very large aneurism. The largest recorded burst externally at the umbilicus.—Referred to special committee.

Solid Ovarian Tumour.—Dr. G. MURRAY exhibited an ovarian tumour which was solid in character. Possibly it was malignant. It came from a lady, 48 years of age, who had been ill for six or seven years. Six months ago, he first saw her; at that time, she was much emaciated and cachectic. Tapping was performed five times. About fourteen pints of fluid came away on the two first occasions. The amount of fluid lessened finally. The kidneys were healthy. A hard mass could be detected *per vaginam*.—Dr. ARTHUR FARKE thought it might be malignant. The uterus had a subperitoneal fibroid growth. The cervix was elongated, and contained a mucous plug.—Referred to Morbid Growths Committee.

Cancer of Kidney and Liver.—Dr. DOWSE exhibited a cancer of the kidney, with secondary cancer of the liver. No albumen had ever been detected in the urine. Ascites and a gall-bladder full of gall-stones were found on *post mortem* examination. The right kidney formed a cancerous cyst, which filled the right lumbar region. The right lobe of the liver contained a carcinomatous tumour.

MEDICAL SOCIETY OF LONDON.

MONDAY, DECEMBER 7TH, 1874.

A. E. SANSON, M.D., Vice-President, in the Chair.

Cleft Palate.—Mr. ROYES BELL showed, for Mr. HENRY SMITH, a boy, born with a hare-lip and cleft soft and hard palate, who had been operated on according to Sir William Fergusson's plan, with considerable success.

Scirrhus Tumour of the Breast.—Mr. WILLIAM ALLINGHAM exhibited a scirrhus tumour of the breast, removed from a woman aged 64, by the elastic ligature. Needles had been introduced, and the ligature applied without pain and without anaesthetics; the process occupied seventeen days, and was unaccompanied by any rise of temperature or other unfavourable symptom; and the patient made a complete recovery. White India-rubber was used. The wound being freely dressed with carbolic oil and other antiseptics, no puridity existed.

Epidemic Sore-throat.—Dr. ROUTH read a paper on an epidemic of infectious sore-throat which occurred in a public institution, and the probable causes of its production. After a tribute to Dr. Farquharson, who had preceded him last session on an analogous subject to the present, the author first gave a description of the institution and its sanitary appliances, where every means had been taken to secure ventilation and a good supply of water and food, and also the unexceptional cleanliness of the girls who were the inmates. Effective means were likewise always at hand in case of infectious disorders arising, and great care was taken to prevent as far as possible their introduction. One case of typhoid fever occurred in October 1873. The patient was removed to the Middlesex Hospital, and ultimately died there. This was after the return of the inmates from the seaside. On the introduction of a new matron a little while afterwards, the sore-throat disease broke out, synchronously with measles and erysipelas. The appearance of measles was explained by the inmates occupying seats in an ill-ventilated church, where a school then seriously affected with this epidemic had been sitting in the morning. One of the erysipelas cases was subject to the disease; but all the others occurred when the throat-epidemic was at its height. One died suddenly with symptoms of sickness and exhaustion. The sore-throat epidemic, of which there were forty-six cases, exhibited three types: simple cynanche; diphtheritic patches; and scarlet fever. When Dr. Routh left London in September, all the sanitary appliances were reported, on inspection, to be in good order. The scarlet fever cases occurred in the charge of Mr. Cheyne. Then, on inspection being again made, the water was found impure; and the filter, having been meddled with, was no longer effective. The drains in the garden were said to be offensive. One fact was noted: of the six matrons, it was the one who drank water only who was affected with severe cynanche. Of the six monitors, all escaped save one, and she also was a water-drinker. Dr. Routh then proceeded to show that other sources of infection had not been disregarded: viz., (1) visitors; (2) infection at the seaside. But, on full inquiry made, no such infection could be traced. He concluded by urging for discussion the following questions. 1. Were the three diseases of the throat coexistent but different affections, or the same disease? 2. Was the erysipelas

produced by a similar miasm? 3. Could the sewage-tainted water have produced the disease—notably the scarlet fever? 4. Had the typhoid fever influence then prevailing in London any influence in the production of this epidemic?—Dr. HAVILAND HALL was sure that had sewage might give rise to various forms of disease, and cited one instance where peritonitis and erysipelas arose from an escape of sewer-gas in a public institution.—Dr. FARQUHARSON was of opinion that the first class of Dr. Routh's cases had nothing to do with the last class, and were quite distinct.—Mr. BRIDENELL CARTER thought that the paper demonstrated the perils of water-drinking.—Dr. CRISP, as illustrating the connection between diphtheria and sewage, gave an instance of a house in Devonshire where nine children died within a month from a species of diphtheria quite unknown in the neighbourhood. On investigation, the drainage of the house was found to pass into a pond, the water of which the children drank.—Mr. CHILYNE had charge of Dr. Routh's cases in his absence, and distinguished three forms of disease: 1. A pure scarlatinal case; 2. Cases of sore-throat, devoid of rash or high temperature; 3. Cases of erysipelatous sore-throat. The drinking-water was the only cause of disease which could be demonstrated, as no proof of contagion existed.—Dr. BUCHANAN noticed that the gap of fourteen days which intervened between the first and second batches of cases precluded any idea of infection. He had no doubt that both scarlatina and diphtheria had appeared in the home; and that they prevailed together, he was certain. Some of the cases had evidently nothing to do with either of these diseases, but must be classed with the erysipelas which appeared. He thought that a form of sore-throat of the same character as the well known hospital sore-throat, but non-specific in kind, might and did arise from septic causes, such as the presence of putrid matter. As for the exact source of this epidemic, it appeared to be traceable to sewage. The institution was flooded with sewer-inhalations; and, instead of the ventilation purifying the air, it probably assisted in freely diffusing the sewer-gas through the building. There being two methods of infection in this instance—the water and the air—it was difficult to distinguish which was the agent; but the erysipelas might arise from septic matter dissolved in water. Ample evidence existed. In the epidemic outbreak at the Patriotic Asylum last autumn, erysipelas came on, followed by a curious form of peritonitis, which the late Dr. Anstie thought he traced to water-poison.—Dr. THEODORE WILLIAMS inquired the amount of cubic space allowed per head in the building, and whether natural ventilation was relied on. If it were, there was little chance of keeping a crowded institution pure and wholesome. He had no doubt of the existence of sore-throat non-specific in character and arising from septic causes, and had noticed instances of it occurring chiefly among servants, who occupied the basement of houses, and therefore were in closer proximity to the drains.—Dr. ROUTH, in reply, said that both the beginning and the ending of the epidemic were characterised by erysipelas. Notwithstanding all that had been said, he saw no case made out for attributing the disease to anything else than poisoned water. The treatment consisted of effervescing salines, gargles containing chloride of potash, and the local use of tannin.

MONDAY, DECEMBER 14TH, 1874.

F. J. GANT, F.R.C.S., Vice-President, in the Chair.

Cleft Palate.—Mr. WILLIAM ROSE brought forward a case of cleft palate, on which he had operated successfully. The patient, a young man, aged 23, came under his charge about three months ago. He had a fissure extending through the soft and hard palate, to within half an inch of the alveolar ridge. He spoke of the development of the upper jaw and palate, which he illustrated by diagrams, and suggested a plan of bringing the maxillæ together immediately after birth, in cases of very wide cleft. He described Sir William Fergusson's method of operating, for simultaneous closure of fissures in the hard and soft palate (a drawing of which was shown) by boring holes through the margin of the hard palate for the passage of the threads, and then cutting through it with a chisel in a line parallel to, and about half an inch from the edge of, the cleft; and also spoke of Sir William Fergusson's introduction of myotomy in the treatment of fissure in the soft palate.—Mr. HILNEY SMITH said that he had assisted in most of Sir W. Fergusson's operations. In the early ones, operation on the soft palate alone was attempted, and the results were not so favourable as under the new plan of osteotomy. The natural covering was far superior to artificial ones; he thought Mr. Rose's case was thoroughly successful, the fissures in the hard and soft palate being completely closed.—Mr. OAKLEY COLES considered that the time was coming when the mechanical treatment of cleft palate would be obsolete. The great drawback in the surgical result was that the patients seldom spoke intelligibly. He remembered one instance only where speech became perfect after the opera-

tion. Failure was attributable to the fact that the free border of the soft palate in these cases never reached far enough back to touch the pharynx and act as an effective valve; and here the mechanical appliance was far more successful.—Mr. THOMAS BRYANT wished to know whether, in the infant, silver sutures had actually been passed through the maxillæ to bring the fissure together. There was no difficulty in piercing the hard or soft palate, but in passing the stitches through, on account of the bleeding. Mr. Bryant introduced the stitches first, which reduced an operation of half an hour to a few minutes. He had some doubt as to the dividing of the levator palati muscle in every case, but thought a division of the pillars of the fauces was an improvement.—Mr. ROYES BELL stated that the speech in this case, though varying, continued to improve; the patient could sing. The hæmorrhage in these cases was much less than formerly.—Mr. FRANCIS MASON remarked that Sir Wm. Fergusson's success was greater since he had divided the bone; previously he had used an angular knife instead of Langenbeck's raspator, and the sloughing of the parts was due, he thought, to his taking too thin a portion off. The maxillæ had been brought together in an infant in America.—Dr. VANDERVEER (America), said that, at Boston, Dr. Warren had tried Sir W. Fergusson's operation, and failed. He had also attempted it, and had succeeded in uniting the soft palate, but not the hard.—Mr. OAKLEY COLES said that Dr. Crombie recommended the galvanic cautery for dividing the bone, as causing less hæmorrhage.—Dr. DRYSDALE thought that obturators were very suitable for improving the voice.—After a few remarks from Mr. Acton, Mr. Mason, and the Chairman, Mr. Rose replied.

GLASGOW PATHOLOGICAL AND CLINICAL SOCIETY.

TUESDAY, DECEMBER 8TH, 1874.

JOSEPH COATS, M.D., Vice-President, in the Chair.

Morbid Specimens.—Dr. HECTOR C. CAMERON showed a limb which he had removed for acute necrosis of the whole shaft of the tibia in a boy.—Mr. W. J. FLEMING showed a tumour of the mamma, which he was inclined to regard as a cysto-sarcoma.

Mediastinal Tumour.—Dr. McCALL ANDERSON showed a patient under his care at the Western Infirmary, aged 44, an iron-moulder by trade, but who had served in the Army from his twenty-fourth to his thirty-sixth year. He had suffered from cough for twelve months, and for six months there had been blood in his sputa, like red currant jelly; for three months he had suffered from swelling of the neck, dyspnoea on exertion, with giddiness and sense of suffocation, especially on stooping to lift weights. Some pain in the right breast and shoulder had existed for a year, and this was aggravated by any hard work. He had followed his employment till three weeks before his admission on November 11th. While in the Army, he had indulged freely in stimulants. He had some form of venereal disease (gonorrhoea with bubo, he said) twenty years ago; and of late a node on the right tibia, with nocturnal pains, had appeared. There was considerable enlargement, with induration of the inguinal glands, and a slighter affection in the arms. At the right apex, defective movement, dullness on percussion, increased resistance, tubular breathing, and increased vocal resonance, were present; the dullness extended beyond the left margin of the sternum. At the right base, feeble respiration existed without any dullness on percussion. The superficial veins of the face, neck, and right upper arm were much dilated, and there was œdema of the face, neck, and upper part of the chest. The right radial pulse was weaker than the left; but no pulsation, murmur, tremor, or other signs of aneurism, could be discovered. The patient was a fine healthy-looking man, without any night-sweats, diarrhoea, etc. Dr. Anderson thought the symptoms and physical signs pointed to some tumour in the mediastinum, part of which might be causing obstruction to the entrance of air into the bronchi, giving rise thus to the feeble respiration at the right base. He thought, from the patient's history, that possibly the tumour was syphilitic. The treatment had been by rest and palliatives, and, on the appearance of the node, iodide of potassium and iron had been given, with a certain amount of benefit. Dr. Anderson, in his remarks, referred to a somewhat similar case reported by him in the *Glasgow Medical Journal*, February 1872. The patient now shown had a well marked true cheloid tumour situated at the mid-sternum, and said to be congenital.

Colloid Tumour of Mamma.—Dr. GEORGE BUCHANAN exhibited a specimen of colloid tumour of the mamma, which he had recently removed from an old lady aged 70. He had noticed the tumour about six months before Dr. Buchanan had seen it, since which it had grown considerably. The operation was attended with success, in so far that the wound cicatrised perfectly in three weeks, and no trace of the dis-

case was then apparent. The tumour was about the size of an American apple, elastic, and circumscribed by an envelope of condensed areolar tissue, septa of which divided it into lobules. To the naked eye, it had the appearance at the circumference of very firm jelly, of a pale pink colour, while toward the centre it was exactly like the pulp of a grape.—Dr. THOMAS REID described the microscopic appearances. At the periphery, there were collections of epithelial cells in alveoli, composed of connective tissue. Nearer the centre, there was a gradual conversion into the proper colloid structure. The colloid substance, he considered, was developed from the connective tissue, the epithelium being surrounded by the colloid, and gradually disappearing.—Dr. JOSEPH COATS believed the structure at the periphery to be cancerous, the epithelial cells in the alveoli being almost typical. He also considered that it was by the conversion of these epithelial or cancer-cells that the colloid material was formed, the peripheral cells first degenerating and then the more central ones.

Malignant Tumour on Chest-wall.—Dr. PERRY exhibited a malignant tumour removed *post-mortem* from the surface of the chest of a female 36 years of age. The tumour had occupied the region of the chest, extending from the outer margin of the mammary gland to the axilla on the left side. It had commenced nine months ago, and was first seen by a surgeon in Paris, who had regarded it as a simple tumour, and recommended no surgical interference. A similar opinion was given shortly afterwards by a surgeon in London. The tumour increased in size, and became an open sore about four months ago. The spongy fungous centre of the tumour gradually sloughed out, and left its centre deeply excavated to within a few lines of the outer surface of the ribs. Frequent hemorrhage took place, but this was easily checked by the use of perchloride of iron. The edges of the tumour had an indurated and scirrhous-like feeling, and were everted towards the lower border. The tumour measured five inches and a half in diameter. The mammary gland was not involved. The cervical glands were not enlarged, and the axillary glands were not affected until within three weeks of death, when slight enlargement appeared. The patient was much emaciated, and death was by exhaustion. Sections of the tumour had been made by Mr. W. J. Fleming, and he desired the opinions of the members as to its nature.—Dr. JOSEPH COATS was of opinion that he case was one of soft cancer. The stroma was distinct, and the cells small, but of very various shapes.

CORRESPONDENCE.

SIR WILLIAM FERGUSSON AND THE NORWICH PROSECUTION.

SIR,—The letter of explanation from Sir William Fergusson, which you published in your impression of last week, seems to me to call for the very gravest consideration.

Briefly to dissect the statements in this unparalleled production, it appears that Sir William Fergusson's defence of his conduct in travelling to Norwich to lend the weight of his official reputation and dignity to this prosecution, is divisible into two heads.

1. That he was not aware that among the defendants were some of his own countrymen who, from their official connections, could obtain powerful assistance in defending themselves and resent his persecution, but that he thought the only person whose character he was assailing was a defenceless foreigner—a distinguished physician invited to these shores by the Association of which he (Sir William Fergusson) was president, who came confident of their hospitality, and endeavoured to repay it by imparting, in response to their invitation, some of the knowledge which he believed himself to possess, and by taking their opinion as to certain results which he desired to place before their eyes. These still await confirmation, but, if adopted, will add much new knowledge of certain complex phenomena of disease. Will any one admit, in such a case, the plea that "it was only a Frenchman"? That is really the gist of this first article of defence.

2. The second plea is, that "my views were squeezed from me by force of law". To this it is only necessary to reply, that there is no force of law adequate to the pressure or intended for the purpose. Sir William Fergusson is no novice in courts of law: he is well aware that no one subpoenas an unwilling witness to attend in the capacity of an expert. Sir William Fergusson was not present at the lecture of Dr. Magnan, and, as is very apparent from his evidence, had only the vaguest information on the whole subject. He attended as an expert in cruelty: and it is unnecessary to remind him, in the words of the ordinary text-book of the schools, that "in *Betts v. Cufford* (Warwick Lent assizes, 1858) the late Lord Campbell stated, in answer to a question, that a *scientific witness* was not bound to attend upon being served

with a subpoena, and that he ought not to be subpoenaed. He could not be compelled to give his attendance to speak to matters of opinion." It is impossible, therefore, to divine by what process of law Sir William Fergusson's opinion was squeezed out of him.

I do not like to express what I feel: but every well-educated medical man must, I think, with me, blush with shame and indignation to find a gentleman assisting in such a prosecution, and giving as his reason for alleging cruelty, the following: "As to whether such an experiment would benefit science, Sir William Fergusson was of opinion that it would not, as it was not likely that one person would inject alcohol or absinthe into the vein of another." Here, sir, is ignorance of which a medical student would be ashamed.

No doubt, it is long since Sir William Fergusson went to school; but when a past President of the British Medical Association, and a Fellow of the Royal Society, boldly announcing himself as one of the best physiologists, makes such an exhibition in a court of law, and employs the weight of his position to bring obloquy upon his fellows—English or French, associates or invited guests—he ought surely to know the alphabet of the subject of which he speaks. To be consistent, Sir William Fergusson must now persecute every physiologist in Europe: there is not one who will not tell him that intravenous injection is the most precious instrument of physiological investigation in the discovery of the mode of action of toxic and therapeutical substances.

It is unquestionably desirable that the British Medical Association and the Royal Society should free themselves from the discredit which Sir William Fergusson has inflicted upon them in his quality as a member of both.—Yours truly,

PHYSIOLOGIST.

SIR,—Sir William Fergusson observes, in the letter which he writes to Dr. Copeman, and of which he has furnished you with a copy for publication, that he is as well entitled to his opinion as the Norwich Committee. No one can doubt this. But the question is, not whether he is entitled to an opinion, but, he being so entitled, and holding positions which make the public utterance of his opinions matters of public and professional importance, what sort of opinions they are which he holds and publicly expresses, and what response shall be made to these opinions. If he is entitled to utter them, he is also responsible for their reasonableness and for the use which he makes of them.

The "opinion" which he went down to Norwich to express was, that the injection of absinthe and alcohol into the veins of a dog was an act of cruelty deserving legal punishment; the *use* which he made of this "opinion" was to abet and support the criminal prosecution of four Secretaries of the British Medical Association, of which he was President, in the town in which they reside; and the *reason* which he gives for it is, that the demonstration of these effects was useless. "BECAUSE no man would think of injecting alcohol or absinthe into the veins of another".

If such evidence had not been given in a very serious manner on a very serious occasion, it might be supposed to be a wild joke. On such an occasion, and used for such purposes, the rash levity and superficial ignorance of such a statement are bewildering. It is impossible not to feel that very cordial reparation is due to the Norwich Secretaries and to M. Magnan for the shocking and unprovoked injury inflicted on them by the eccentricities of Sir William Fergusson. The Académie des Sciences has presented M. Magnan with a premium of £100 for his researches. What will the British Medical Association do to show to M. Magnan and to their Norwich Secretaries their sense of the injustice which has been done to them? Something, I beg, for the honour of our profession; and that before long.

I am, etc.,

NORFOLK.

MALARIA.

SIR,—When I find a scientific man beginning with Bacon and his idols, or with the persecutions of Galileo, I pull a long breath and prepare for the worst. Such was my sensation when I found Dr. Inman placing Bacon in front of his argument in his letter to you last week. After a similar prelude, some twenty years ago, I heard a F.R.C.S. Eng. startle the Medical Society of London by reading a paper to prove that infection had nothing to do with gonorrhœa. His theory was, that men returning home at night felt symptoms of vesical distension, and turned down some lane or mews and unavoidably exposed a most unoffending organ to the keen wind, which brought on a cold and a muco-purulent discharge: that, under such circumstances, it was a toss up whether a man caught cold in his nose or in the unmentionable part; and that there was no more infection in gonorrhœa than in coryza. As I am not supposed to know anything about malaria, Dr. Inman will not

mind my expressing the belief that this "glacial" theory of ague will not fare better than the "glacial" theory of gonorrhoea. If the shock of cold to the heated body be the sufficient cause of ague, why is there so little in England? and why in London does it not produce one and the same form of ague, instead of half a dozen different varieties? For one man who catches ague from lying down hot on the ground he has disturbed, some thousand in tropical countries get ague they know not how, except that they were under paludal influences. It was not only the navvies who had ague when Paris was being transformed, but many well-to-do folks, who could not explain the occurrence, except that they lived near the disturbed ground. This was the case with a friend of mine, a *professeur agrégé* of the Paris Faculty of Medicine, who, being in good health, and never having had ague, had a severe attack of it when they dug up the Rue Louis le Grand, where he lived, to put it down in asphalté. Those who believe in the telluric origin of ague are the first to admit that cold intensifies the action of the unknown poison.

I am, etc., EDWARD J. TILT.

Grosvenor Street, January 1875.

THE HAMPSTEAD HOSPITAL.

SIR,—The inhabitants of Hampstead and St. Pancras know only too well, whatever may be said to the contrary, how small-pox spread among them after the Hampstead Hospital was opened. They also know how greatly property has depreciated; how houses have been left in the carcase since 1871; how some have been pulled down and the materials sold. Things had just, however, begun to recover, when, to our intense disappointment, it has been decided to build a permanent hospital. All is panic again. Whether there be a sufficient cause for this panic or not, Hampstead will well nigh be ruined, and property depreciated at least 30 per cent. The numerous schools and lodging-houses will be closed, building operations cease, and Hampstead utterly lose its prestige. I am still of opinion that infectious diseases can be conveyed through the air. Will, however, some of the members of our Association kindly answer the following questions, so as to enable us to come to a right conclusion on this matter?

1. Can infection be conveyed through the air, and disease induced, without direct contact? If so, to what extent? 2. Can infection be conveyed by currents of air and atmospheric dispersion, in common with aroma, miasma, and offensive smells? 3. Is a clay soil in a hollow more conducive to the spread of infection than a gravel or chalk soil on an elevated situation? 4. Is it right to let the feculent discharges from patients suffering from infectious diseases pass into the common sewer? When disinfected, is there not great difficulty in depending on their effectual disinfection when diluted by the general drainage of a large hospital?

Surely many of our precautions are unnecessary, if infection cannot be conveyed, even to considerable distances, through the air, especially when favoured by currents of air; precautions, such as fires in the sick rooms—even in summer, not only for ventilation, but to carry a current of air away from the house; also cloths steeped in disinfectants and hung over the door.

The unsettled state of opinion as to the nature of infection, and the limit of its dispersion, shows it to be, to say the least, an open question. All facts, therefore, bearing on this question will conduce to a more definite and satisfactory solution of this difficult subject.

I am, etc., STEPHEN S. ALFORD, F.R.C.S.

Haverstock Hill, January 5th, 1875.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

THE Great Varmonth Board of Guardians have increased the salary of Mr. John C. Smith, the Medical Officer to the Workhouse, from £80 to £120 *per annum*.

POOR-LAW MEDICAL APPOINTMENTS.

CRUICKSHANK, Thomas A., M.R.C.S. Eng., appointed Medical Officer and Public Vaccinator for the Ekeston or No. 3 District of the Basford Union, Nottinghamshire, vice A. B. Norman, F.R.C.P. Ed., resigned.
 HENRY, Thomas E., L.R.C.P. Ed., appointed Medical Officer and Public Vaccinator for the Leek District and the Workhouse of the Leek Union.
 DUNSTON, W. M., Esq., appointed Medical Officer for No. 1 District of the Woodbridge Union, vice R. Palmer, Esq., resigned.
 ELLIOTT, G. F. F., L.R.C.P. Ed., appointed Medical Officer for the Second District of the Bromyard Union, vice R. Morley, M.R.C.S. Eng., resigned.

FORBES, Duncan M'Donald, L.R.C.P. Ed., appointed Medical Officer and Public Vaccinator for No. 1 District of the Basford Union.

M'ARTHUR, Peter, M.B., appointed Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Grey Abbey Dispensary District of the Newtownards Union, co. Down, vice Greer, deceased.

MCCLURE, Thomas, L.R.C.P. Ed., appointed Medical Officer for the Second District of the Axbridge Union, vice E. Dodd, M.R.C.S. Eng., resigned.

M'KEOWN, William, L.R.C.P. Ed., appointed Medical Officer, etc., for the Dirraw Dispensary District of Ballymoney Union, co. Antrim.

ROBERTSON, Edward B., M.B., appointed Medical Officer to the Stepney Union Workhouse, Bromley.

PACKARD, Joseph, M.R.C.S. Eng., appointed Medical Officer and Public Vaccinator for No. 7 District of the Blything Union.

POWELL, Wm., M.R.C.S. Eng., appointed Medical Officer for the First District and Workhouse of the Bromyard Union, vice R. Morley, M.R.C.S. Eng., resigned.

SMYTH, Wm. J., M.D., appointed medical officer and Public Vaccinator for the No. 7 or Shipley District of the North Brierley Union.

SETTON, Frederick, M.R.C.S. Eng., appointed Medical Officer for the Willingham District, Guinsborough Union, vice J. C. B. Smallman, deceased.

TREHARNE, John, M.B., appointed Medical Officer for the newly formed No. 13 or Windhill District of the North Brierley Union.

WHITE, John B., M.D., appointed Resident Medical Officer to the Infirmary, Hackney Union.

APPOINTMENTS OF SUPERINTENDENT MEDICAL OFFICERS OF HEALTH IN IRELAND.

VESEY, Agmon Blathwayt, L.K.Q.C.P.I., appointed to the Magherafelt Rural Sanitary District, co. Londonderry.

MILITARY AND NAVAL MEDICAL SERVICES.

DR. DE CHAUMONT'S PAMPHLET ON THE ARMY MEDICAL DEPARTMENT.

SIR,—In reply to the letters which appeared in the JOURNAL of December 12th, I wish to say that I am still of opinion that Dr. De Chaumont would have been better advised if he had not written his pamphlet until he was prepared to put before the members of his profession the *whole*, and not a *part*, of the question into which he entered. He has in one column put forward as prominently as possible the so-called advantages of the service, including the 43 per cent.; and all he has said on the other side is, that there is an excessive mortality, and that the chances of becoming an administrative officer are remote. He never mentions the many serious disadvantages under which his brother officers labour, and which they are anxious to have redressed. War-Office officials do not generally trouble themselves to distinguish between the real and the apparent gain. When they see an officer of the department say the apparent gain of the warrant of 1873 is 43 per cent. greater than that of 1804, they say at once, "Why, here these fellows have got a great deal more pay than they did seventy years ago, and yet they are not satisfied". It is just like the old surgeon, who will tell you, if you complain, "Why, sir, you should consider yourselves very lucky. I only got 7s. 6d. when I entered the service." We judge a warrant by its pay and retirement tables. An increase in the sums granted is a real, not an apparent gain. The pay and allowances of a military surgeon, spread over the first twenty years of his service, are only £302 *per annum*; his voluntary retirement, only £219 yearly after the completion of this period. I have not entered into the prospective advantages, because, according to your correspondent's own confession, they are infinitesimal. A chance of one in thirty, or, in money value, of £6 or £7 *per annum*, can scarcely be called an advantage. I have pointed out that, in many instances, it is almost impossible for an officer to live and bring up a family upon such a wretched emolument; and this is the common sense and practical way of looking at the matter.

Think you the War Office care about the mortality among medical officers? No. As long as they can get others to fill their places, they will merely shake their heads, if they ever had any, and say, "How very sad! We really must do something for these poor fellows." But the something never comes. The pressure of public opinion can alone gain for the service a proper status, a quicker promotion, and a better retirement. To obtain these should be objects of legitimate pride to us all. These will not be obtained by half-hearted advocacy and faint praise, but by a "strong pull, a long pull, and a pull altogether". By an effort of this kind, we may yet hope to see our profession occupy its proper position in the Army. It must be always a quiet one, but on that account not the less useful and honoured. We feel we have the sympathy of all in attempting to obtain this end. We should have the hostility of none, for it is a fair ambition and an object of legitimate effort. Having, in a former letter, almost exhausted the subject, I must conclude by apologising for having trespassed so much on your space.

I am, etc., LONGA EST INJURIA.

NAVAL MEDICAL APPOINTMENTS.

BURKE, Surgeon John, to the *Swiftsure*.
 DREW, Surgeon J. B., to the *Flora*, additional, for service in Ascension.
 DUKE, Surgeon Valentine, to the Portsmouth Division of the Royal Marines.
 GRANT, Surgeon Robert, to the *Hector*.
 ISAAC, Surgeon J. B., to the *Duke of Wellington*.
 SWEETMAN, Staff-Surgeon Stephen, second-class, to the *For*, additional, in lieu of a Surgeon.

We incline to think that Dr. Mackenzie's best course will be to apply to Dr. Monar, who advises on these matters in places not in the metropolis. We do not think that any authoritative statement from the Local Government Board has been made on these points.

OBITUARY.

EDWARD WILLSON DUFFIN, M.D., F.R.C.S.

EDWARD WILLSON DUFFIN was born at Halifax, Yorkshire, in April, 1800. In 1817, he matriculated at the University of Edinburgh, where he subsequently graduated in 1821. He became a Fellow of the Edinburgh College of Surgeons in the year following. He first started in practice in Edinburgh. It was mainly through his exertions that the Dispensary for Diseases of the Skin in that city was founded. At that time, he wrote several pamphlets on cutaneous subjects, and especially an essay on Squamous Disorders. In conjunction with the late Professor Lizars, he prepared and collected a number of life-size drawings of Skin-Diseases. After two years, his health failed, and he was recommended to winter in Italy. He passed two years at Florence, and ultimately settled in London in 1828.

He was among the earliest introducers of the operation for strabismus. He pointed out the advantages of a small conjunctival wound, of regulating the amount of muscle divided, and of operating on both eyes in cases of alternate squint. In 1847, he published a work on *Deformities of the Spine*, pointing out especially the utility of graduated muscular exercise in the correction of lateral deformities. In 1850, he operated successfully, and by a new method, on a case of ovarian tumour. In a paper published in the 34th vol. of the *Medico-Chirurgical Transactions*, he insisted upon the great value of the following modifications in the operative procedure then in vogue:—1, making a relatively small incision in the median line of the abdomen; 2, tying the pedicle of the tumour into the mouth of the wound, so as to keep all the cut surfaces extraperitoneal, avoid enclosing ligatures and acquiring greater control over subsequent hæmorrhage; 3, narcotising the patient with opium, and keeping her well under its influence for many days after the operation; 4, keeping a relatively hot moist atmosphere about the patient.

In 1855, Dr. Duffin was elected a Fellow of the London College of Surgeons. He continued in active practice till about 1868, when the infirmities of advancing age compelled him to retire. He was a Fellow of several learned societies.

He died at the residence of his son, after a short illness, of pneumonia, consequent upon renal disease, in the 75th year of his age.

THOMAS ANDERSON, M.D., F.R.S.E.,

LATE PROFESSOR OF CHEMISTRY IN THE UNIVERSITY OF GLASGOW. DR. ANDERSON died on November 2nd, at the age of 55, at Chiswick. He was born in 1819, and was educated at the University of Edinburgh, where he displayed great interest in the study of chemistry. On leaving college, the desire of prosecuting his favourite pursuit led him to Stockholm, where for some time he studied under Berzelius. Removing afterwards to Germany, he enjoyed at Giessen the prelections of Liebig, besides visiting Berlin and other towns for the purpose of attending lectures or obtaining interviews with all the more celebrated Professors of Chemistry. Returning to Edinburgh, he commenced the teaching of chemistry in the Extramural Medical School. His class attracted attention all over the country, and several of the students who there had the benefit of his instruction have risen to high positions as chemists. Latterly, his fame extended beyond this country, and in his classes were to be found a considerable number of foreign students. The departments of chemistry to which Dr. Anderson had devoted special attention were those relating to agriculture and the products of coal-tar and opium. He had few, if any, equals. In 1848, he was appointed Consulting Chemist to the Highland and Agricultural Society. In 1852, he received from the Crown the appointment of Professor of Chemistry in the University of Glasgow, in succession to Dr. Thomas Thomson. In the university, Dr. Anderson found ample scope for the exercise of his talents as a teacher. The duties of his chair Dr. Anderson continued to discharge with great acceptance till 1869, when he had

a paralytic seizure, which incapacitated him for work. In May last, Dr. Anderson had another stroke of paralysis, and resigned his professorship in July, when Mr. Ferguson was appointed to the chair with his former teacher's cordial approval. Dr. Anderson is survived by Mrs. Anderson and two sons.

JOHN TEMPLETON KIRKWOOD, L.F.P.S.G., M.R.C.S.

MR. KIRKWOOD was born in the town of Ayr in 1812. After a liberal education at the academy of the town, he studied medicine and surgery at the University of Glasgow. He then took the licence of the Faculty of Physicians and Surgeons, and almost immediately joined the Medical Staff of the British Auxiliary Legion, then being raised in this country to support the rights of the Infant Queen Isabella II against Don Carlos. Under Sir De Lacy Evans, Mr. Kirkwood acted for two years with great distinction, gaining two decorations for medical services in the field. In Captain Ball's *Narrative of Seven Years in Spain*, Mr. Kirkwood is spoken of with great praise. On the return of the Legion, Mr. Kirkwood bought a practice in the then thickly inhabited and busy suburb of Somers Town. Here he practised for many years with great success. He was appointed as Medical Officer to the Sick Fund of the Great Northern Railway Company in London, and, after a long and useful service in that capacity, became the Company's Medical Officer in town. When the Midland Company (for which he also acted) demolished Somers Town for their Grand Terminus, Mr. Kirkwood's surgery was removed to Euston Road. Here he continued to practise until his retirement from active life two years and a half ago. He married in 1855, and leaves a widow, but no family. His contributions to medical literature are "A Treatise on Croup," "Papers on the Malignant Fever in Vittoria, 1835-6," and on the "State of the Hospitals in the British Legion." He was by nature generous, kind-hearted, ready to help, and a firm friend. After retirement, he fell into delicate health, and died at Ayr Villa, Maida Vale, on October 7th. He was buried in Paddington Cemetery, Willesden, his remains being followed by a few of his most intimate friends.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, December 31st, 1874.

Clarke, Henry, Penge Park, Anerley
 Crouch, Ernest John, Lewisham, Kent
 Grosholz, Frederick Hermann Varley, Walkden, Bolton

MEDICAL VACANCIES.

THE following vacancies are announced:—
 ARMY MEDICAL DEPARTMENT.—Surgeons. Applications to be made to the Director-General of the Army Medical Department.
 ATHY UNION, co. Kildare.—Medical Officer and Public Vaccinator. Salary, £120 and fees.
 BAKEWELL UNION.—Medical Officer for the Bakewell District and Workhouse. Salary, £25 and £36 per annum respectively.
 BALLACHULISH SLATE QUARRIES.—Medical Officer. Salary, £200 per annum. Testimonials to be sent in to J. Gardner, Ballachulish, N.B., on or before the 14th inst.
 BECKETT HOSPITAL AND DISPENSARY, Barnsley.—House-Surgeon. Salary, £140 per annum, with furnished rooms, gas, and coals.
 BIRMINGHAM GENERAL DISPENSARY.—Resident Surgeon. Salary, £130 per annum, with furnished apartments, coals, light, and attendance. Applications on or before the 20th inst.
 BLACKBURN UNION.—Medical Officer for the Harwood District. Salary, £75 per annum.
 BRADFORD UNION.—Medical Officer for the Workhouse. Salary, £225 per annum.
 BRIDGWATER UNION.—Medical Officer for No. 2 District. Salary, £70 per annum.
 CASTLE WARD UNION.—Medical Officer for the Ponteland District. Salary, £20 per annum. Also, the Workhouse. Salary, £30 per annum.
 DERBYSHIRE GENERAL INFIRMARY.—Assistant House-Surgeon. Board, lodging, and washing, but no salary. Applications to Secretary.
 ESSEX LUNATIC ASYLUM.—Second Assistant Medical Officer and Dispenser. Salary, £100 per annum, with board, lodging, and washing.
 FIFE AND KINROSS DISTRICT ASYLUM.—Assistant Physicianship. Salary, £80, with board, etc. Apply to Dr. Fraser, Medical Superintendent, Cupar-Fife.
 GREAT NORTHERN HOSPITAL, Caledonian Road.—One Physician and one Surgeon. Applications to be sent in on or before January 12th, 1875.
 HARRIS, Parochial Board of.—Surgeon. Salary, £60 per annum, including vaccination and medicine for the poor. The gentleman elected will get £200 per annum for attending the ratepayers and cottars within South Harris. Applications to be made to the Chairman of the Parochial Board of Harris.
 HEADINGTON UNION.—Medical Officer for the Wheatley District. Salary, £70 per annum.
 HITCHIN UNION.—Medical Officer for the Workhouse. Salary, £55 per annum.

INDIAN MEDICAL SERVICE—Twenty appointments as Surgeon. Examination in February 1875.

LEEK UNION—Medical Officer for the Endon District. Salary, £20 per annum.

LICHFIELD UNION—Medical Officer for the Alrewas District. Salary, £35 per annum.

LOCHMAREN, Parish of, Dumfriesshire—Medical Officer. Salary, £50 per annum, and fees. Testimonials to be lodged with the Inspector of Poor on or before the 16th instant.

METROPOLITAN ASYLUM DISTRICT—Medical Superintendent of a temporary Asylum for Imbecile Children. Salary, £400 per annum, with furnished house, coal, and gas. Applications on or before the 13th instant.

MIDDLESEX LUNATIC ASYLUM, Hanwell—Assistant Medical Officer.

MITFORD AND LAUNDITCH UNION—Medical Officer for the Workhouse. Salary, £45 per annum.

NORTH BRISTLEY UNION—Medical Officer for the Seventh District.

NORTH-EASTERN HOSPITAL FOR SICK CHILDREN, Hackney Road, E.—House-Surgeon. Salary, £100 per annum, with attendance, rooms, coal, and light.

NORTH WALES COUNTY LUNATIC ASYLUM—Assistant Medical Officer. Salary, £100 per annum, with board, lodging, and washing. Applications to be sent in on or before the 13th instant.

OKFHAMPTON UNION—Medical Officer for No. 1 District. Salary, £35 per annum. Applications to be made on or before the 22nd instant.

PLYMOUTH UNION—Medical Officer for No. 3 District.

POPLAR AND STEPNEY SICK ASYLUM DISTRICT—Assistant Medical Officer to the Asylum.

REDDITCH AND DISTRICT MEDICAL ASSOCIATION—Medical Officer. Salary, £150 per annum, with fees and unfurnished house.

ROYAL FREE HOSPITAL—Junior House-Surgeon.

RYDE DISPENSARY—Physician.

SCARBOROUGH UNION—Medical Officer and Public Vaccinator to the Sherburn District. Salary, £35 per annum, and fees. Applications to be made on or before the 13th inst.

ST. BARTHOLOMEW'S HOSPITAL—Assistant Physician.

ST. LUKE'S HOSPITAL FOR LUNATICS—Second Clinical Assistant. Board and furnished apartments.

SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY—House-Surgeon. Salary, £100 per annum, with board, lodging, gas, and washing.

SMALLBROUGH UNION—Medical Officer for the Ludham District. Salary, £55 per annum.

STRAFFORD-ON-AVON UNION—Medical Officer for the Welford District and Workhouse. Salary, £50 per annum.

STRATHKINNESS, Village and District of—Medical Officer. Salary, £10 from Parochial Board, with £110 from a workmen's club, exclusive of midwifery fees. Apply to Mr. A. Cowper, Kincaid, Cupar Fife.

SWANSEA URBAN AND PORT SANITARY DISTRICT—Medical Officer of Health. Salary, £200 per annum, and fees.

TENDRING UNION—Medical Officer for the First and Second Districts. Salary, £97 per annum.

TORPHINS in the Parish of Kincardine O'Neil, Aberdeenshire—Parochial Medical Officer: £45 per annum. Applications to Chairman of Parochial Board.

TOWN'S HOSPITAL AND ASYLUM, Glasgow—Medical Assistant. Salary, £80 per annum, with board and lodging. Applications on or before the 2nd instant.

TRINITY COLLEGE, Dublin—Professor of Chemistry: £500 per annum, and fees. Applications to the Rev. Dr. Haughton, Trinity College.

TYNEMOUTH UNION—Vaccination Officer.

UNIVERSITY OF EDINBURGH—Additional Examiner in Medicine.

WHITBY DISTRICT LOCAL BOARD—Medical Officer of Health. Applications to be sent in on or before the 14th instant.

WOOLWICH UNION, Kent—Assistant Medical Officer to the new Infirmary at Plumstead. Salary, £60 per annum, with board, lodging, and washing. An additional salary of £50 per annum will be given for dispensing for the poor of the Plumstead District.

WORCESTER UNION—Medical Officer for No. 2 District. Salary, £45 per ann.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

DAV, Edmund O., M.R.C.S. Eng., appointed Resident Medical Officer to the Royal Infirmary for Children and Women, Waterloo Bridge Road.

DRKE, Douglas W., M.R.C.S. Eng., appointed Surgeon to the East Sussex, Hastings, and St. Leonard's Infirmary.

HARRIES, Thomas D., M.R.C.S. Eng., appointed Surgeon to the Aberystwith and Cardiganshire General Infirmary.

SHAPLEY, H. T., M.R.C.S., appointed Resident Accoucheur to the London Hospital, vice R. N. Idewellyn, Esq.

TIMBERY, Robert, M.D., appointed House-Surgeon to the Male Lock Hospital, Dean Street.

WADDE, Thomas H., M.R.C.S. Eng., appointed Surgeon to the East Sussex, Hastings, and St. Leonard's Infirmary.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.

MARRIAGE.

SCHÖN-VENABLES.—On January 6th, at Christ Church, Brondesbury, N. W., by the Rev. Canon Venables of Lincoln, uncle of the bride, James Edward Schön, M.R.C.S. Eng., to Ellen Emma, eldest daughter of the late George Henry Venables, Esq., of Warley Lodge, Brondesbury.

VACCINATION.—An award of £100 2s., from the Local Government Board, for efficient vaccination, was received on the 1st instant by Mr. W. E. G. Pearse, public vaccinator for the Westminster district. A grant of £8 has been awarded to Mr. K. Jocelyn Swan, for vaccination efficiently performed in the second district of the union of Northfleet.

OPERATION DAYS AT THE HOSPITALS.

MONDAY Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

TUESDAY Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

WEDNESDAY St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaitan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

THURSDAY St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

FRIDAY Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.

SATURDAY St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—East London Hospital for Children, 2 P.M.—Hospital for Women, 9.30 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M.—Royal Free, 9 A.M. and 2 P.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY.—Medical Society of London, 8.30 P.M. Mr. Henry Smith, "On a Case of Cancerous Tumour involving the Tibia requiring Amputation"; Mr. Thomas Bryant, "On the least Sacrifice of Parts as a Leading Principle of Surgical Practice".

TUESDAY.—Royal Medical and Chirurgical Society, 8.30 P.M. Dr. George Thin, "On the Pathology of Lupus Erythematosus"; Dr. Haynes, "On an Epidemic of Malarious Yellow Fever on board H.M.S. *Doris*, off Port Royal, 1873".

WEDNESDAY.—Hunterian Society, 7.30 P.M.: Council Meeting, 8 P.M.: Dr. Hughlings Jackson, "On Mental Disorders after Epileptic Seizures". Mr. F. M. Corner will show a patient the subject of a Primary Resection of the Ankle-joint, and a case of Wound of the Spine with Symptoms of Lesion on one side—Epidemiological Society, 8 P.M. Dr. Arthur Ransome, "On the Relations between Diphtheria and Scarlet Fever" (will be read by the Secretary).

FRIDAY.—Medical Microscopical Society, 8 P.M. Annual General Meeting for election of officers and other business.

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with Duplicate Copies.

AUTHORS desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor: those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

M. D. will feel obliged if any of our readers will inform him whether he is entitled to claim a fee in the following case. A lady told him, when in attendance on a member of her family, that she would soon require his services, as she was near her confinement; but no particulars as to fee or time were mentioned. The next time M. D. called, she declined to see him; and also on two future occasions. He then wrote and asked whether he had given her any offence. She replied, that she was perfectly pleased with him as a medical man, and would send for him when she required him. She has since been confined, but not by M. D.
* * * Certainly not.

FOREIGN DEGREES.

SIR.—Having but lately spent some time in Germany, and taken the degree of M.D. at the University of Giessen, I feel able and justified in contradicting the statement of your correspondent "Physician" in the JOURNAL of December 10th, that this degree *can* be and is *alone* obtained by examination in English; for, by my intimacy with all the medical faculty, I know as a fact that but one of the professors can speak the English language in even the most broken and imperfect manner. This difference between Giessen and other German Universities, pointed out by your correspondent, therefore, in conferring degrees, does not at present exist.
Stockport, Dec. 22nd, 1874. I am, etc., M.D. GIESSEN.

H. M.—Dr. (?) Lockyer was a great quack of the time of Charles II. His reclining effigies, in thick curled wig and furred gown, were to be seen in the Lady Chapel, Southwark, with his epitaph:

"His virtues and his pills are so well known,
That envy can't confine them under stone," etc.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

MANAGEMENT OF NERVES OF THE TEETH.

SIR,—As the heading of the report of the paper which I read before the Medical Society of London on November 16th, published in last week's JOURNAL, conveys to the minds of your readers not an indistinct or incorrect impression of the subject, but its direct antithesis, I shall esteem it a favour if you will, in your next issue, give prominence to this letter, calling attention to the fact, and reasserting my convictions of the importance of the statement which I did make—viz., that the retention of the nerves of the teeth should be the first and paramount object of the operator under all circumstances; that it is one that may be successfully attained under some I gave, I hope, satisfactory evidence—I am, sir, faithfully yours,

WILLIAM DONALD NAPIER.
22, George Street, Hanover Square, December 30th, 1874.

LEICESTER SQUARE.—John Hunter lived on the east side of Leicester Square, next door to what is now the Sablonière Hotel. On the west side lived William Cruikshank, whose daughter married Honoratus Leigh Thomas, President of the Royal College of Surgeons, who resided in Leicester Place.

PHYSICIANS AND INFIRMARIES.

SIR,—I cannot let what you say with regard to general practitioners holding M.D. degrees being appointed physicians to public institutions pass without a strong protest. The title of physician is so associated in the public mind with that of the consultant, that to give a general practitioner such a position would be to give him a most unfair advantage over his brethren. At the institution and in the public mind he would rank above the surgeons, whilst in private practice he would be their competitor; and naturally, if the public could have the physician to an infirmity for the same fee as their ordinary medical attendant, what chance would the latter stand in comparison with the former? I am sure no physician should ever be appointed to any charity, unless he give up all surgical and obstetric practice as well as dispensing. If such a person cannot be obtained, let the officer doing the medical work be called medical officer. The governors of all the local charities here have always acted in accordance with these views, and I believe they are concurred in by the Branch I have the honour to represent.—I am, sir, your obedient servant.

JOHN WOODMAN, F.R.C.S. (by Exam.).

Exeter, Jan. 2nd, 1875.

* * * We only stated a matter of fact, and we have to add now that every Licentiate of a College of Physicians is a "physician".

DERMATOLOGIST.—We were once informed by the late Dr. Scott that a dessert-spoonful of the chlorate of soda, put into each basin of water with which the person washes, will remove the icteric hue of the skin.

ON THE RIGHT MANAGEMENT OF THE PUERPERAL STATE.

SIR,—Cases of parturition continually occur in which there is neither protracted suffering, nor to any appreciable extent, loss of blood. In such cases, I venture to predict that the profession will not be long in arriving at the conviction that the graduated cold douche, applied at the conclusion of labour, is a measure strictly scientific, and capable, under favourable circumstances, of effecting the very best results; nor will the practice probably be restricted to such cases. So far as the local application of cold shall continue to be esteemed a remedy proper and expedient for the arrest of the hæmorrhage incidental to childbirth, so far may the douche, or some modification of it, applied to the spine, still be found the most effectual method for the application of cold. Indeed, I have long since arrived at the conviction that in such cases the routine practice of applying wet cloths to the abdomen is both physiologically wrong and capable of producing disastrous results. For the right suggestion in this, as in many other instances, the profession is indebted to the intelligent observers of former times, who, when they wanted to arrest a hæmorrhage, put a cold key down the patient's back. In doing this, it is very probable they were actuated by no theory, though in reality the practice was in accordance with the true theory—the influence of the spinal cord in regulating the temperature of the body, and thereby arresting hæmorrhage and other abnormal conditions.

I am, etc.,

M.D.

Harlesden, January 1875.

FUNGUS OF THE EXTERNAL EAR.

SIR,—In the JOURNAL of December 26th, I observe a memorandum on the above subject. If personal experience should be of any interest, the following is my own. Nearly seven years ago, I suffered for some months from irritation of both ears, brought on by sea-bathing. It commenced in the right ear, the first intimation being a frequent "popping" at night, when lying on it, coming on during sleep and rousing me, and relieved by turning to the other side. In November, after I had given up the bathing, the left ear also began the "popping", with considerable irritation throughout the day. Thinking a little warm oil might relieve it, I dropped some in during the evening, and put in some cotton-wool; then my sufferings began—acute inflammation, profuse discharge, perforation of the tympanum, deafness. I went to London and consulted an aurist. He syringed the ear, blew a gale through it, and put in some cotton-wool. To this last I rather objected, expressing my idea that it had caused the previous inflammation. He thought it unlikely, and wished me to keep it in while on a railway journey of two hours. I agreed, but in less than an hour the pain returned in real earnest. I threw the wool out of the carriage-window, and the pain subsided. The aurist wished me to have the ear syringed every day, and for a time I did so. On one occasion I was surprised to see a dark object, having the size and appearance of a ripe apple pip, floating on the water. Under the microscope, I found it to consist of a perfect network of fungus, resembling the aspergillus. A few days later, another portion came away, but I never found any afterwards. As the syringing was always followed by pain and discharge, I gave it up. The hearing improved to a certain extent, and I never suffer any pain in the ear now.

I mounted two specimens of the fungus in glycerine, intending to show them to the aurist; but on my acquainting him, by letter, of the circumstance, he did not appear to attach such importance to it as I was disposed to, so I never showed them. Not having examined them since till now, I find they have not improved by keeping, though they may still be recognised. I may remark, that unbleached lambs'-wool produces no irritation, and that I have never advised cotton-wool since.

I am, etc.,

D. McD.

December 29th, 1874.

NOTICE TO ADVERTISERS.—Advertisements for insertion in the BRITISH MEDICAL JOURNAL, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than *Thursday*, twelve o'clock.

THE CLINICAL SOCIETY'S REPORT.

SIR,—In the report of a meeting of the Clinical Society at page 819 of your JOURNAL, a short speech is attributed to me. I certainly did not make it, for I was not at the meeting. The error is probably one for which the printer alone is responsible; but, as it may lead to misunderstanding, I must ask you to allow me to correct it.—Yours, etc.,

JONATHAN HUTCHINSON.

15, Cavendish Square, W., January 2nd, 1875.

SIR,—A writer in the *Lancet* has gone out of his way to comment upon the report of a meeting of the Clinical Society which appeared in your JOURNAL of the 26th ultimo. I was unavoidably absent from the meeting in question, but subsequently received, in due course, the authors' MSS. of the abstracts of papers read at the meeting. And I then availed myself of the printed discussion therein which appeared at once in the *Lancet* to complete the report, intending when I next met my fellow-reporter at the Society to express to him my thanks for the same. I have furnished slips to a reporter of the *Lancet* when he has been absent, and, on the above occasion, certainly did not anticipate any objection to my using in the same way a report which had already been published. Such courtesies as these, I presume, are not uncommon in the case of journalism generally.

The innuendo conveyed by the writer of the paragraph in question, that the reports which appear in your JOURNAL are not usually original, nor the work of your own special staff, you and your readers fortunately know to be false.

January 1874.

Yours faithfully,

YOUR REPORTER.

* * * THE BRITISH MEDICAL JOURNAL employs a staff of three special reporters for the metropolitan medical societies. It has also its own reporters in Edinburgh, Dublin, Liverpool, and other great cities. No other medical journal has an equal or similar staff for the purpose.

ARE THE LONDON HOSPITALS ON CLAY?

SIR,—In a note appended to a letter from one of your correspondents *BRITISH MEDICAL JOURNAL*, January 2nd, 1875) on the vexed question of the proposed Hampstead Hospital, it is stated that "nearly every London hospital" is on a clay soil. Surely, the writer of that note is entirely unacquainted with the soil on which the greater part of London—celebrated from the time of the Romans to the present day for the excellence of its soil and situation in reference to health—is built. The fact is, that, from Barking and Woolwich on the east, to Wandsworth and Twickenham on the west, on both sides of the Thames, in a width of from one to three miles, there is a deep fine gravelly soil, beneath which only is the well known London clay. So far from nearly all the London hospitals being built, as it is technically called, "on a clay soil", the reverse is the case. On the north side of the Thames, beginning at the east, we find the London Hospital, St. Bartholomew's, King's College, Westminster, St. George's—all built on a fine bed of gravel; whilst on the south side, Greenwich Hospital, Guy's, the modern St. Thomas's—are all on gravel. If this be true of our large hospitals, it must be true of the majority of the smaller ones, beginning with the Poplar and Victoria Park Hospitals on the east, and ending with the West London at Hammersmith.

I am less certain as to the North London, the Middlesex, and St. Mary's, which may or may not be situated on the border of the clay district, which includes part of Bayswater, Westbourne Park, Regent's Park, St. John's Wood, Holloway, and Hampstead.

If any faults of construction or of situation of our London hospitals, consequent upon their age and the exceeding growth of the metropolis, exist, do not allow the unjust stigma of their being built upon a clay soil to pass uncontradicted. Note also the wisdom of our ancestors in the choice of soil and situation. Nearly all the large hospitals which I have enumerated were erected upwards of one hundred and twenty-five years ago, and were then situated amidst green fields, or in the near neighbourhood of them. A glance at any map of London of over one hundred years ago will confirm this statement.

I am, Sir, your obedient servant.

January 1874.

M.D.

* * * Our correspondent evidently mistakes sand for gravel. It is quite true that there is a superstratum of "drift, gravel, and sand" over the clay under most of the hospitals he has mentioned; but true gravel is limited to a small part of Hampstead and Highgate, as reference to any geological map will show.

A VET. AND M.R.C.S.—"A skillful leech is better far

Than half a hundred men of war."

So sang Homer, on Machaon's being wounded, as translated by Pope.

"A wise physician, skill'd our wounds to heal,

Is more than armies to the public weal."

Chaucer and Spenser, however, use the word "leech" for the spiritual physician. Farriers were called "horse-leeches"; and persons skilled in the distempers of cows and other horned cattle are, in several countries, to this day called "cow-leeches".

MEDICAL DEGREES AND TITLES.

SIR,—I have read with mixed feelings of amusement and indignation the correspondence that has been going on in the JOURNAL on the subject of the assumption of the title of Dr. by L.R.C.P.s: amusement at the sophistry of the writers, and indignation that members of an honourable profession should be yet not willing but anxious to live their lives in a false position. I happen to know a L.R.C.P. who puts Dr. on his cards and doors. I often fancy I should like to look into his letter-box and see how many of his correspondents call him M.D. Your correspondents make great capital of the fact, that the public call all medical men "doctors", and argue from that, that they, the public, do not know the difference between a degree and a license. My experience leads to the opposite conclusion. The public call us "doctors" because it is a convenient mode of address, and because they think we like it; but I confidently assert that nine out of ten men of average education know right well the difference, and do without hesitation define the two positions accurately.

The facts of the case appear to me to lie in a very narrow compass. The title of Dr. belongs only of right to the holder of a degree, and that degree is a guarantee to the public that the holder has studied and passed an examination in all subjects, a knowledge of which is considered necessary by the University of which he is a graduate. A license, on the contrary, informs the public of nothing, and it may concern that the holder of it possesses the minimum knowledge, which the law permits a man to practise medicine. If he possess more than the minimum, it is for him to convince the public that he does so.

There are doubtless cases, such as those mentioned by Mr. Manby, when the possession of a degree would be of the utmost advantage to a man in high class practice who wishes to pass on into pure physics; but I would ask your correspondents to simply state the value of a degree to the ordinary general practitioner; I would also ask them to instance any case in which the acquisition of a degree has been of any signal service to a general practitioner, of course excepting the information acquired by the necessary study. Again, should the Universities agree to grant degrees to all men now in practice who are willing to go up for examination (there is no fear, by the way, of the Universities doing so), what would be the result? A general disturbance of the whole state and condition of our profession for a few years, and then the adoption of some higher title to distinguish men of superior attainments. There must be grades in our profession, and those grades must be maintained; and I for one should be sorry to see any attempt at communism amongst us.

In conclusion, I must enter my protest against the almost universal statement that it is the L.R.C.P.s of Edinburgh that most usually assume this title, for I find that Licentiates of all the Colleges, with the sole exception of London, do it, and probably to a greater extent than the Edinburgh ones.

Apologising for occupying so much space, I am, etc.

ONE WHO STUDIED AT AN UNIVERSITY, BUT TOOK THE

L.R.C.P. EDIN.

December 1874.

SIR.—Pardon my adding another to the already too many letters written upon the subject; but as one who holds neither degree nor license, I may, as an outsider, make one or two remarks in reply to three of your correspondents. "L.R.C.P. Ed." says his qualification "cannot be obtained by a few hours' examination"; but he, perhaps, does not know that a M.R.C.S., L.S.A. Lond., has to undergo only one hour's written and twenty minutes' *extra* examination for that honour. To the observation of "Honestas," that "examination-tests for Licenses of Colleges of Physicians are no more strict than those for L.S.A.," I would reply that he cannot have any knowledge of the London College, as the standard for its license is much higher than the standard of half the Universities in the United Kingdom. The examination-papers will prove it, combined with the class of candidates, and the average number of rejections. To an "University Man" I would say, that M.D. is certainly lower than F.R.C.P. Lond., and even in many cases than M.R.C.P. Lond.

There are different classes of M.D.s, and also of L.R.C.P.; and, to my mind, the Scotch M.D.s (excepting Edinburgh) are, certainly, as far as proofs by examination go, below either M.R.C.P. or L.R.C.P. of London. Oxford and Cambridge degrees in medicine—conveying, generally, the fact that the holders are gentlemen, and, to a certain extent, classical scholars—deservedly stand first; and even London, though requiring much more knowledge of, and hard work in, medical subjects than either of the latter Universities, cannot quite hold her head as high. Edinburgh, and Trinity College, Dublin, come next, and even head the list in their respective sections of the kingdom; but for the graduates of the remaining British Universities to aspire to take the same standing is, I think, as presumptuous as for a L.R.C.P. Ed. to put himself on a par with a L.R.C.P. Lond.

December 28th, 1874.

Yours, etc.,

IGUALDAD ANTE LA LEI.

SIR.—Permit me a short space to reply to the communication signed "L.R.C.P. Edin." in your issue of December 10th, especially as it impugns some of my statements in a former letter (facts I still maintain, and am prepared to prove), as well as meaning to annihilate me utterly.

First, I do not write in "ignorance," nor with any intention "to convey a false impression as to the requirements of the Royal College of Physicians of Edinburgh as to their license." I write after a four years' residence and curriculum in Edinburgh, and not as some gentlemen, whose only information is derived from a short and solitary visit to Edinburgh to obtain the L.R.C.P. Nor do I wish to undervalue the Edinburgh College of Physicians, for which I entertain a great respect, and with some of whose examiners, and many of whose licentiates and members, I am on intimate terms; also, let me say I place proper value and honour on the "double qualification" obtained there. My objections are entirely and solely levelled at the L.R.C.P. granted after examination to the men already possessing a diploma, when, in the words of the regulations, "candidates are at once admitted to the second part of the examination," and consequently are entirely excused the first; and so I insist, as an already doubly qualified man. When I went up for the M.D. Edin., I had to pass a far more severe examination, or rather sets of examinations, for my "degree," than I should have had to take the L.R.C.P., notwithstanding what "L.R.C.P. Edin." so stoutly maintains: so I am anything but "quite mistaken." And that the examinations are nothing like "identical," either as far as the number of subjects required, or length of time, etc., can easily be proved by any one who looks into the *Medical Directory*, and it is well known to every resident medical student in Edinburgh. Again, the examiners of the University require, as I was officially informed and proved, the same quality and number of marks for their written and oral questions from all candidates (with no abatement of subjects), whether they already possess one, two, three, or no qualification at all, not to name a subsequent examination after the M.D. in Greek, logic, etc.; so how can it be "as difficult to get the L.R.C.P. as the M.D. Edin."? And if men are equally entitled to be called Doctors, why work for the latter when the former is much more easily obtained; and does it not show the considered honour of the M.D. when the Senatus of the University never address their M.D.s by the title of "Dr."? Now, I think I have shown it is "less difficult" to write L.R.C.P. Edin. than M.D. Edin. after your name; besides, what of that "year of grace," or, as it was wittily called, "year of disgrace," when any qualified man was admitted to the L.R.C.P. Edin. without any examination at all? I can quite believe some solitary M.D. Edin. may have been plucked for the L.R.C.P. & S. Edin.; but that double qualification is not the question. I am talking of the L.R.C.P. Edin. as given to men already with a diploma, and who mostly obtain it "to call themselves Doctors." A man may just get through at one place, and just fail at another; besides, occasionally it happens that a good man may be plucked, and a bad man pass.

I know that the examination mortality for the M.D. Edin. is very high—sometimes near 50 per cent.; and I should like to know what proportion of already qualified men fail at the L.R.C.P. Edin. In my own experience, I do not know of one, but I have known many very moderately-up men go in and win, and amongst my own acquaintance (aye, and on my recommendation), some even who dreaded "the Hall," and took L.R.C.P. instead, merely for the double qualification; but, when obtained (much to their surprise and gratification), they astonished their friends by saying they had taken "a degree in Edinburgh," and then altered their door-plates and cards to "Dr."

Now, again, I ask "L.R.C.P. Edin."—Is that license "as thorough a test of medical and classical knowledge, etc., as the M.D. Edin.?" and is it "on a par

with any other Scotch qualification"? I am sure the *cognoscenti* would all say, certainly not. If the title of Doctor be of no importance, then why all this hubbub and unjust assumption of it, and why do doubly qualified men leave England, take a few days' trip to Scotland, and return calling themselves Doctors?

Of course, the public may, and do, call all medical men frequently Doctors, not depending, as "L.R.C.P." seems to say, on "having a medical title," but simply as being a doctor by profession, just as a lawyer, etc.; and so, in a sense, they are Doctors—"the doctor called in." Still, that does not give a man the right to assume the title, and call himself Doctor, unless he could reply to the question, Doctor of what?

The comparison as to the "two marquises" is absurd, because both are unquestionably acknowledged and understood as such, and do not clash: one sits in the Lords as a Peer, the other does not; one has the title and the deeds, the other only the title. In short, their positions are properly defined; while if any qualified man is to call himself Dr., how can the public discriminate, and what is the use of the extra study and time in obtaining the M.D.? Surely, it is more than "the difference between tweedledum and tweedledee."—I am, yours,

January 1874.

M.D. EDIN.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Birmingham Daily Gazette; The Western Daily Press; The Manchester Guardian; The Ulster Advertiser; The Sussex Coast Mercury; The Broad Arrow; The Surrey Advertiser; The Bedale and Northallerton Times; The Hackney Express; The Liverpool Porcupine; The Scotsman; The Liverpool Mercury; The Glasgow Herald; The Stroud News and Gloucestershire Advertiser; The Bradford Observer; The Morpeth Herald; The Portsmouth Times; The Western Daily Press; The York Herald; The Sheffield Evening Star; The Brighton Guardian; The Sussex Daily News; The Wrexham Advertiser; The Glasgow Herald; The Sussex Coast News; The Finsbury Conservative; The Berkshire Chronicle; The Hull News; The Southern Times; etc.

LECTURES

ON

THE OCCURRENCE OF ORGANIC FORMS
IN CONNECTION WITH CONTAGIOUS
AND INFECTIVE DISEASES.*Delivered at Owens College, Manchester.*

BY

J. BURDON SANDERSON, M.D. V.P.R.S.,

Jodrell Professor of Physiology in University College, etc.

LECTURE I.

THE subject of the present lecture is the relation of bacteria to the chemical and physical processes which constitute the life of the higher animals.

One of the first questions which suggests itself to the mind in approaching the subject is this: How does it happen that these bacteria, which we suppose must have existed half-a-dozen years ago in as great numbers as at present, were then scarcely heard of, and that they now occupy so large a place in the medical literature of this country and of Germany, and have lately afforded material for lively discussion in the French Academy? To us in England the subject is chiefly associated with the truly scientific investigations of Lister—the first to show its practical bearing on the pathology of traumatic diseases. In Germany, there can be no doubt that the extensive inquiry which is now being carried on by so many persons, took its start from the laborious researches of a poor professor of botany at Jena, who, with defective resources, bad instruments, and in spite of discouragement and disparagement of all kinds, has persisted for many years in his strivings to work out this intricate question. Unfortunately, he lost his way at an early stage of his enterprise, and, like many pioneers in exploration, has accumulated results of which it must be admitted that the value is scarcely proportional to the quantity. Need we be surprised that, of the many who are quite ready to sneer at Hallier and his cholera-fungus, few, if any, have undergone the labour of reading his papers?

As introductory to my subject, I must first give a short account of the natural history of the organic forms which we now, following high botanical authority, group together under the term bacteria. Secondly, I shall consider the question of their general influence on the processes of life of the higher animals, and the mode in which this is exercised. This will prepare us for discussing the question how far they act as morbid poisons, or as the vehicles of such poisons, or are characteristic of specific diseases. I would remind you that the question we have before us is not that of the origin of bacteria, nor that of their place in nature, but the more restricted one of their influence on ourselves, and on the lower animals whose life, whose health, and whose diseases are but the counterparts of our own.

It is because they are constantly invading our bodies and attacking the living protoplasm by which the work of life is carried on in our tissues, that we, as pathologists, take an interest in their natural history. It is for this reason that questions relating to them, which at first sight seem recondite and remote, have a direct and immediate bearing on practical questions. For if, as I shall endeavour to show, they are constantly present to us—constantly mixing up their life with ours—we cannot wisely remain ignorant of their nature. We do not aspire or profess to be botanists; but, if plant-forms and plant-life associate themselves with the very processes which it is our business to study, we must become botanists for the occasion.

In the short introductory account I shall give of the forms of bacteria, I shall follow Professor Cohn (*Ueber Bacterien, die kleinsten lebenden Wesen*, Berlin, 1872), as being the only botanist of high authority who has given special attention to the subject. For the remainder of what I intend to say, I am myself answerable. I shall, however, make it my endeavour not to vindicate the views which I have advanced myself, or which others may have attributed to me; but to place before you a general view of the work that has been done during the four years which have elapsed since the subject began to occupy the serious attention of pathologists.

MORPHOLOGY AND NATURAL HISTORY OF BACTERIA.

The first fact that I shall advance with respect to bacteria is, that they are the smallest and least organised of all living beings. As regards size, it is best to judge by comparison with objects with which we are microscopically familiar. The most common rod-like forms are

in length about one-third of the width of a blood-corpuscle; *i.e.*, about $\frac{1}{1000}$ th of an inch—so small that, if we examine a liquid containing them, with the ordinary magnifying powers used for histological observations, we can scarcely be said to see them to any practical purpose. It is necessary to have recourse to the best microscopes and the highest powers, if it be desired to observe them in such a way as to arrive at useful results.

What grounds have we for stating that they are the lowest organisms? One is, that they present only very slight differentiation of parts; but in this sense they are certainly not simpler than many other forms that might be referred to. The chief ground for the statement lies in this, that they are much less *specific* in their characters—much more under the influence of the conditions under which they originate and are developed—than organisms of any other class. Just as in the higher animals and in man himself we call those functions lowest which are most completely automatic—*i.e.*, most completely under the guidance of known conditions—so also, as regards form, we recognise that while all animal and vegetable forms, even the highest, are moulded by circumstances to fit their places in the economy of nature, this moulding power—this adaptation of form to circumstance—becomes more and more obvious the lower we descend in the scale of development.

The next fact relates to the *habitat* of bacteria—to the medium in which they live—water. They inhabit water either as such in the ordinary sense, or in the various conditions recognised as *moisture*, whether occurring on damp surfaces or as filling the interstices of solid bodies, which bodies, when so impregnated with water, are said to be damp. Those who are familiar with chemical work, know that this quality of dampness goes a great deal further than the popular notion of it; that many things ordinarily called dry, yield, when subjected to the drying processes commonly used in the laboratory, evidences of being really moist. Consequently, moisture, regarded as a limiting condition of bacterial life, is a very wide and comprehensive one.

From this statement, it must not be understood that bacteria do not exist in the atmosphere. But their existence there in an active form strictly depends on moisture. They attach themselves, without doubt, to those minute particles which, scarcely visible in ordinary light, appear as motes in the sunbeam, or in the beam of the electric lamp. It is by the agency of these particles that they are conveyed from place to place.

Notwithstanding that the word bacterium means a rod, and that many of the forms to be immediately referred to are not rod-like, I am obliged to use it, because it is used by others as a general term for the whole group of organisms known to botanists as *Schizomycetes*. This designation being obviously too long, I attempted, in 1870, to introduce the word *microzymas*, a word which was intended to denote the fact that, in the development of these organisms, the process of vegetation is always associated with chemical processes of a peculiar kind, in a way comparable to that in which the vegetation of the yeast-plant is associated with the alcoholic fermentation. I forego the use of the word microzyme for the reason I have mentioned, *viz.*, that it has not been taken to, but I am not the less sensible that such a word is as much needed now as ever; for it is evidently inconvenient to say, as I now find myself compelled to say, that bacteria—rods—may be either globular, egg-shaped, or filamentous. Cohn classifies our organisms under terms expressive of these various forms, the most important being micrococcus, bacterium, vibrio, and spirillum. I have drawn these on the black board.

Bacteria have, as a rule, two states of existence—a state of activity and a state of rest. When a liquid teeming with bacteria in the active state is observed under the microscope, the attention is so riveted, that it is an effort to take away the eye from the instrument. The movements have been often described. In the case of rod-shaped bacteria, the axial movement in which the rod advances or retreats in the line of its axis, the direction being frequently reversed, is the most common. This kind of locomotion occurs often by fits and starts, the body remaining in the intervals quite still, or assuming a pirouetting or spinning movement. In all rod-like bacteria, it is probable that the progressive or axial movement is associated with rotation, for, in observing the motion of vibrios, it is easy to see that they, in progressing, twist round the axis of the spiral. When this is the case, it looks as if the filament were executing a wriggling motion, *i.e.*, as if its body were contractile; but this is obviously deceptive. The mechanism of the motion is as little understood as those of *Oscillatoria*, which it closely resembles. It must be carefully distinguished from the passive motions which are exhibited by all particles of size comparable to that of bacteria, when suspended in a liquid of which the density does not differ very widely from their own. We shall find afterwards that certain forms of bacteria appear to be motionless in all stages of their existence.

Reil-bacteria multiply by repeated bisection. This mode of multiplication goes on continuously, the rate varying with the conditions of life, and particularly with temperature. Under favourable circumstances, it is enormous. From actual measurement of the time which elapses in a single case between a bisection and the division of each half into quarters (in other words, of the longest time that a single bacterium remains without dividing), it has been ascertained that the interval in question, in common bacteria is about an hour. This being the case, it is easy to compute that every single bacterium must produce 16,777,220 individuals in twenty-four hours. Putting it otherwise, the progeny of a mass of bacteria weighing $\frac{1}{1000}$ grain would, at the end of a day, weigh a pound.

In the largest forms of bacteria, it can be made out that each individual consists, not, like an animal cell, of one sort of living substance,* but, like a plant-cell, of a protoplasmic interior enclosed in an envelope of cellulose, by virtue of which the bodies of bacteria are enabled to resist the action of reagents, particularly weak acids and alkalies, which dissolve protoplasm. In those bacteria which separate from each other as soon as they assume the form of distinct individuals, the more stable external part presents itself as a mere envelope; but when, as very usually happens, the progeny which results from a continuous succession of divisions remains in a state of aggregation, the envelope appears to become identified with the "gelatinous" matrix by which they are held together. This observation was made more than twenty years ago by Cohn, who devised the term *zoogloea* as a general designation for the clumps, or, as Hallier calls them from the mode of aggregation above described, "colonies". You will find that this term is now very constantly used by writers on the subject, for these gelatinous masses occur under a great variety of circumstances. In form, they are mostly either spheroidal or membranous, and have this one characteristic which is noteworthy, that their structure is such as to indicate that they grow at their surfaces or margins, not interstitially. Thus, for example, in the spheroidal forms, which, as seen under the microscope, present a more or less circular outline, it is obvious that the multiplication of individuals is most active near the edge. The membranous forms, on the other hand, often present a growing outline in one direction, a disintegrating one in the other.

We are not able to state that the process of repeated division into two is the only one by which bacteria come into existence. When we watch a liquid in which they are beginning to appear as if spontaneously, where none were visible a few minutes before, all that we can make out is, that a nebula presents itself; and that here and there, in the previously homogeneous liquid, particles exist which, although their form is at first indistinguishable, eventually become recognisable as bacteria. As to the way in which this happens, it is difficult to speak positively, for with reference to it no evidence is admissible excepting such as is founded on direct observation—i. e., on watching the process in a single instance for many hours—fixing the eye on a single bacterium, a thing weighing two-billionths of a grain, and measuring one-eighth-thousandth of an inch, and not quitting it till it divides and divides again. Klebs has attempted to do this, but I will not detain you with an account of his researches.

From what I have said as to their structure and ordinary mode of multiplication by division, it is obvious that bacteria resemble plants, and particularly the Oscillatorie, more than animals. The proof that they are plants rests on what is known as the nature of the chemical processes which constitute their life, to the consideration of which we must now pass.

How do bacteria act on the medium in which they live? On this subject, we owe the foundations of our knowledge to Pasteur. The first fact is, that bacteria act on the media in which they live, not as animals, but as plants. Like plants, they derive the nitrogen that they use to build up new albuminous compounds, not from previously existing albuminous compounds, but from ammonia. Like other colourless plants, they derive their carbon apparently from any carbon-compound except carbonic acid, by dissociation of its elements. Like plants, they require certain inorganic constituents to be present in their soil, particularly potash and phosphoric acid.

As regards the assimilation (or fixation) of carbon, Cohn's researches have very materially advanced our knowledge since the publication of Pasteur's work. It was obvious that bacteria did not decompose carbonic acid under the influence of sunlight, by the same wonderful process by which that dissociation is performed by green plants. This they could not do in the absence of chlorophyll. But in this respect they were not

in any different position from the fungi, or even from the colourless phanerogamic parasites—as, for example, the bird's-nest orchis.

Pasteur's investigations* related, not to bacteria or to the organic forms which are associated with the process of putrefaction, but to the yeast-plant. With reference to that organism, he proved that it derives its nitrogen directly from ammonia. He proved at the same time that the cellulose of which the external part of the yeast-cell consists, is derived from grape-sugar, and cannot be formed in the absence of that body. He did not extend the application of these facts to the organisms of putrefaction; but it came to be assumed that what was true of the yeast-plant would also be true of the others—viz., that, although ammonia was a sufficient source of nitrogen, some hydrocarbon must be present to yield carbon.

Cohn showed this assumption to be a mistaken one, by applying to the organisms of putrefying liquids the same mode of investigation that Pasteur had before applied to the yeast-plant (Cohn, *Beiträge zur Biologie der Pflanzen*, Heft ii, pp. 191-202). That method (since known as the method of cultivation) consists in first finding a liquid of known chemical composition in which the plant to be investigated grows vigorously, and then gradually modifying the composition of this liquid by the elimination of one after another of its ingredients, until at last a mixture is obtained in which the greatest possible simplicity is combined with the greatest possible adaptedness as a soil to the requirements of the particular organism; adaptedness being judged of by rapidity of growth. Such a liquid, as regards the yeast-plant, is that known as Pasteur's cultivating fluid. Its composition stands for the fact that sugar and certain crystalline salts are all that is wanted for the nutrition of the yeast-plant.

In the earlier experiments as to the cultivation of bacteria, e.g., in those which I made in 1871, it was assumed that Pasteur's liquid would also be the most suitable liquid for bacteria. During the same year, however, Cohn, observing that, although bacteria flourished in it abundantly, it was very difficult to prevent the growth at the same time of the yeast-fungus and of penicillium, i.e., common mould, left out the sugar, and found that the bacteria flourished better without it than with it. His next step was to substitute for the solution yeast-ash (a material which is troublesome to prepare) a solution containing the required salts in about the proportion in which they are ascertained to exist in the ash of the yeast-plant. The liquid which we now use as a "cultivation liquid" for bacteria is prepared by dissolving half a percentage each of potassic phosphate and magnesic sulphate in water having a trace of calcic phosphate in suspension,† and then adding as required a further percentage of ammonic tartrate, and of course boiling the mixture. In this liquid, bacteria grow rapidly—a fact which proves not only that they are able to take their nitrogen from ammonia, but that they can also derive carbon from the tartrate—the only carbon-containing body which is present. Although, however, it supports the life of bacteria so completely, that they not only subsist in it, but multiply with enormous rapidity under favourable conditions of temperature, it never originates them, if it have been boiled. It can, indeed, be very easily kept for indefinite periods without change, remaining absolutely transparent and barren, provided that care be taken to protect it from contamination. It is, however, much better practically to keep the solution of inorganic salts, adding the tartrate in the proper proportion for each set of experiments.

In order to determine the development of bacteria in a liquid of this kind, all that is necessary is to touch it with a "damp" surface—a glass rod, a thread of cotton or silk—any object which, having been exposed to the atmosphere, has not since its exposure been dried by heating it to a sufficient temperature. The result may be equally well attained by allowing a particle of dust or a drop of water, or common distilled water, to fall into the liquid. All these liquids, although they contain no organic forms which can be recognised even with the aid of the highest powers, yet contain that which, when added to solution of ammonic tartrate, determines its decomposition, and the building up of its nitrogen and carbon into higher combinations—in a word, vegetation. I call this process quasi-spontaneous. It is not spontaneous, for this simple reason—that it is dependent on conditions which are so far known, that it is possible to control them with perfect certainty.

I may add, that it was by experiments such as those to which I have just been referring that I was enabled to show, in 1871, that moist surfaces and particles of solid material in suspension in the air play the chief part in the propagation of bacteria: i.e., in the conveyance of the material out of which they spring from one soil to another. This in-

* In using the expression, "one sort of living substance", I must guard against being supposed to mean that any kind of living protoplasm is homogeneous. Hyaline though it may appear, we are not able at present to assign any limit to its complexity of structure.

* The experiments in question are to be found in Pasteur's well known papers on Alcoholic Fermentation (*Annales de Chimie et de Physique*, tome lviij, 1858).

† The calcic phosphate is best prepared by precipitating solution of calcic chloride with common sodic phosphate, taking care that the former shall be in excess. This precipitate splits on boiling into a soluble and an insoluble phosphate.

ference has now been confirmed—I think I may venture to say, established—by very numerous observations.*

INFLUENCE OF BACTERIAL VEGETATION ON THE PROCESS OF PUTREFACTION.

In referring to Cohn's classification of the organisms which constitute the group of Schizomycetes according to their form, I stated that this classification was chiefly of value for the purposes of description, and that the exact similarity of any two forms cannot here be taken as evidence of their organic continuity any more than their dissimilarity affords indication of the absence of intimate relation between them; for the influence of environment over organisms such as bacteria is so great, that it seems as if it were paramount: the surrounding conditions claiming a power not merely of moulding the organism into conformity with themselves, but even of originating it.

For reasons on which it is unnecessary to enter here, we do not admit the latter part of this claim; but it is a principle of fundamental importance in dealing with the question we have now before us—that of the agency of bacteria in septic processes—that the influence of circumstance over form is practically so powerful, that, in considering the relation of bacteria to septic processes, we shall do best if we regard the appearance of particular forms as mere links in the chain of events of which the process consists.

To illustrate this, it will not be waste of time to refer for a moment to the singular fact discovered a short time ago by Professor Cohn, that, under conditions as yet quite unknown, colouring matters come into existence in albuminous liquids when left to themselves at ordinary temperatures; and that this development of pigment is associated with the development of bacteria. Not long ago, having left a "solution" of ordinary egg-albumen in a cupboard in the laboratory, I found that the liquid, which had no putrid odour, possessed an intense indigo blue colour. Being acquainted with Cohn's observations, I at once guessed what had happened, and found, on microscopical examination, that the blue scum on the surface of the liquid consisted, first, of colourless bacteria, resembling in form those met with in septic liquids; and, secondly, of blue pigment-particles of extreme minuteness, which appeared to be imbedded in the interstitial gelatinous material by which the organisms were surrounded. The process continued for some time; but eventually the liquid was inadvertently allowed to dry. On inoculating a similar albuminous liquid with the dried residue, I was unsuccessful in reproducing the process; but Cohn, who came upon several of his colour-producing bacteria in a similarly accidental way, was able to perpetuate the process by repeated transmissions.†

I mention this observation merely to illustrate what I have been saying as to the relation between the two collateral processes—between the vegetation-process, on the one hand, and that of the formation of a characteristic chemical product, on the other. Here we have no sufficient reason for saying either that the production of colour is the cause of the development of bacteria, or that the bacteria are the agents in the production of the pigment. All that we observe is, that the two phenomena begin, continue, and end together; we regard them, therefore, as collateral characteristics of one and the same process.

As the result of innumerable observations, we know that, as a rule, those changes in albuminous liquids, which we familiarly recognise as constituting putrefaction, are accompanied by the presence in such liquids of characteristic vegetable organisms. We also know that the two processes—viz., the chemical changes and the rapid vegetation go on *pari passu*, and that the same circumstances which favour the growth and multiplication of organic forms also favour putrefaction.

As to the meaning of these facts, there is some difference of opinion even among competent naturalists. All are agreed that the relation between the chemical process and the vegetative process is an intimate one; but somewhat discrepant views prevail as to its nature.

The fundamental experiment by which the intimacy of the association is proved is this. When a tube or flask is partly filled with water containing albuminous matter in solution or suspension, and subsequently boiled for a sufficient length of time, and closed hermetically during ebullition, no putrefaction occurs under any circumstances; but if, after such a tube has been heated and allowed to cool, a drop of distilled water, or any other exposed liquid, be added before the tube is again sealed, putrefaction follows, provided that the preparation is kept at the ordinary temperature.

As I have already hinted, there are some naturalists who would not agree to the terms in which I have stated this result. They would rather substitute for the words "under any circumstances" some such expression as "in 9,999 cases out of 10,000." For our present pur-

pose, it makes little difference whether the statement be accepted absolutely or not. But there is another point relating to the origin of bacteria in albuminous liquids of much greater importance, which the discussion about abiogenesis is apt to conceal, or throw unduly into the background. It is a question which arises directly out of the results of the "cultivation" experiments to which I have just referred. These experiments show that bacteria are able to derive the whole of the carbon they require for the building up of their protoplasm from compounds of great chemical simplicity, which have never formed part of any living organism, and seek for no higher source of nitrogen than ammonia. This being the case, it is more than probable that, when the growth of bacteria goes on in association with septic processes, they derive their nitrogen and carbon, not from the albuminous compounds themselves, but from the ultimate products of their disintegration. This being the case, we must regard bacterial life (in so far as it consists in the building up of new protoplasm) as a process consequent on the chemical process of putrefaction with which it is associated. For disintegration must already have preceded as far as to the production of ammonia—in a word, must have proceeded to the last stage—before the new integration could commence.

While admitting this, it is important clearly to see that the admission does not in any way render it more or less probable that bacteria are the efficient causes of putrefaction—that without which putrefaction could not take place—for there is nothing which forbids us to regard bacterial vegetation as connected (if I may so express myself) with both ends of the chemical process of disintegration of putrescible material at the same time; not the shadow of an objection to the assumption that, on the one hand, bacteria derive material for the integration of their protoplasm from the products of *disintegration* of the soil in which they flourish, and, on the other, that they produce the ferment by which disintegration is determined. There is nothing, in short, against their standing to the chemical process at the same time in the relation of antecedent and consequent.

If it should seem to you that this is a too vague way of dealing with the subject, I would ask you to consider that the question is one in respect of which caution is more than usually necessary: for, while theoretical explanations offer themselves freely on every side, experimental investigation is beset with peculiar difficulties. As regards the main question, that of the agency of bacteria in producing putrefaction, there are two extreme views, which are both clearly mistaken—the one which asserts that they have nothing to do with the septic process; the other, that the chemical phenomena of putrefaction are the mere accidents of a peculiar kind of vegetation. The truth lies without doubt between these two opposed theories; but it is not to be got at by an ingenious reconciliation of the one with the other, but by honestly opening the mind to the facts as they stand, in the confidence that, if they are allowed fair play, they will eventually shape themselves into a general conception, in accordance with their true relation. So long as uncertainty exists, there is nothing to be so much avoided as that sort of clearness which consists in concealing difficulties and overlooking ambiguities.

[Since this lecture was delivered, an important contribution to the elucidation of this question has been made by Dr. Hiller of Berlin ("Der Antheil der Bacterien am Faulnissprocess", *Centralblatt*, No. 34, Nov. 14th, 1874). Starting from the fact observed by himself (to the accuracy of which I can testify from my own observation) that, in the "alkaline fermentation" of urine, the splitting of urea into ammoniac carbonate is not in relation with the abundant development of septic bacteria in the liquid, he made experiments which showed that in urine, bacteria do not derive their nitrogen from urea, but from other sources; and that, if ammoniac tartrate be added to urine, the multiplication of bacteria goes on with great activity without any diminution of its acid reaction, i.e., without any decomposition of its urea. From this result, he proceeds to similar experiments as to the influence of bacteria on egg-albumen. Having first ascertained, by careful observations, the fact familiar to the housewife that fresh eggs "turn" when put into the same basket with rotten ones, and can therefore be infected through the air, he injects a "cultivation liquid", containing bacteria, but not putrid, into the albumen of a fresh egg, with the aid of a subcutaneous syringe. The egg remains unaltered. He therefore thinks it impossible to identify multiplying bacteria with the "septic ferment"; with reference to which he thinks that the experimental investigations of the last few years have proved nothing more than "it is a particulate substance which either exists suspended in the air, or adheres to objects, and that it can be separated from the air by filtration, and can be destroyed by the temperature of ebullition". With this final statement of the case I perfectly agree, and am not at all disposed to quarrel with him because he goes on to suggest that the "particles" of which the septic ferment consists are not living beings, but *Proteinfällchen*.]

* On this subject, see Cohn, *loc. cit.*, p. 194; Landau, *Arch. für Chirurgie*, xvi., p. 531.

MEDICAL ADVERTISING AND MEDICAL REVIEWING.

Abstract of an Address delivered at the Harveian Society of London, January 7th, 1875.

By JAMES R. LANE, F.R.C.S.,

Surgeon to St. Mary's and the Lock Hospitals; President of the Society.

[MR. LANE, after alluding to the difficulties in the choice of a subject suitable for such an occasion, said he had decided to abide by the instructions conveyed in the laws of the Society, and to occupy himself chiefly with its condition and future prospects, and with such events as had occurred during his year of office, which seemed to invite attention and to suggest comment.]

The favourable state of the finances of the Society was a matter for congratulation, and suggested the question whether it was not in a position to increase its sphere of usefulness: and amongst other modes of doing so, he thought the establishment of a Lectureship to be held annually by some member of the Society was well worthy of consideration. After some further remarks, he alluded to certain occurrences which took place in the early part of last year, which he considered worthy of notice on account of their bearings on the dignity and honour of the profession and on the character of medical literature.

In March last, an extraordinary meeting was held, to consider a proposition for the expulsion of a member who had pursued a system of advertisement in the daily papers, which, in the words of the law, was thought to be an "offence against the established usages of the profession".

The advertisements in question, which occupied a whole column in the *Times* and other papers, were of a kind happily hitherto unknown amongst respectable medical practitioners, and that they were derogatory alike to their author, to the Society, and to the profession was generally admitted. Nevertheless, there were members whose opinions were entitled to attention and respect, who urged that the advertisement of medical books in non-medical journals had become one of the established usages of the profession; and that, therefore, the advertisements in question, though deserving of censure, could not fairly be brought within the terms of the law. In the end, the necessary majority of three to one was not obtained, and the motion for expulsion was consequently lost. The result was, the immediate resignation of various official and other members, and the imminent secession of many more, which seemed almost to threaten the disruption of the Society, when fortunately the offending member came to the rescue, and solved the difficulty by his voluntary resignation.]

In commenting on these occurrences, he said: What seems to me most deserving of attention is the fact that there were members of the Society who stated in plain terms that they could not see any essential difference between the advertisements which were held to be so obnoxious, and those of medical works (some of which were mentioned by name), which appear constantly in the *Times* and other non-medical papers; and I think there can be no doubt that a feeling adverse to the practice in any shape is pretty largely entertained throughout the profession. That being so, the custom seems fairly open to criticism and remark; and it may fairly be questioned whether the practice of advertising medical works on disease of all kinds in the daily journals is conducive to the credit and legitimate advantage of the profession.

Far be it from me to presume to hint the smallest blame on those who had availed themselves of a custom which has undoubtedly become one of the established usages of the profession. Amongst them may be found many who are entitled to all honour and respect; it is against the custom only that I venture with all deference to enter an humble protest.

It is worthy of remark that, what may be called the classics of medical literature, works of established repute on medicine, surgery, physiology, and anatomy, and the like, rarely grace the advertising column, though, if the real object were to instruct the public in medicine and the allied sciences, these would seem to be the most appropriate channels through which information might be conveyed. But that column is almost exclusively occupied by announcements of the works of Dr. A. or Mr. B. on this or that particular class of disorders, some of which it is hardly decent to parade upon the daily breakfast-table, for the edification of the wives and daughters of the period. That these

announcements should be made under the regis of respectable publishers, by whom they are ostensibly inserted, in no way alters the principle, or diminishes the responsibility of those whose names are thus put forward.

In the *Essays of Elia*, there is one "On the Two Races of Men", in which Charles Lamb explains that "the human species, according to the best theory he can form of it, is composed of two distinct races, the men who borrow and the men who lend; to which two original diversities may be reduced all the other various impertinent classifications into white men, black men, red men, etc.," and he goes on to demonstrate the infinite superiority of the former (the men who borrow); "they take no more thought than lilies; whereas the latter are born degraded—he shall serve his brethren—and there is something lean and suspicious in his air, contrasting with the open, trusting, generous manners of the other." Somewhat similarly an old teacher of mine divided medical authors into two classes; the men who write for practice, and the men who write from it. He might, paraphrasing Elia, have pointed out the great superiority of the former. "How freely and openly doth he avail himself of the intellectual capital of his inferior brethren, never troubling them with acknowledgment or receipt. What a liberal confounding of the pedantic distinctions between *meum* and *tuum*—what approaches doth he make to the primitive community, to the extent of one-half of the principle, at least. Lend, therefore, cheerfully, O man ordained to lend, that thou lose not in the end the reversion promised."

Now, those who write for practice and those who write from it—those who only want to say something, and those who have something within them which they want to say, both have their representatives in the advertising columns of the daily papers. Will it be thought too presumptuous to suggest to the latter, whose works are really written for the profession and not for the general public, and many of which are an honour alike to their authors and to science, that they might fairly content themselves with the publicity afforded through the medium of the medical press? It cannot be contended that there is any demand for works of this class amongst non-medical readers: the only real effect, then, of such advertisements is to bring the names of their authors prominently before ordinary newspaper readers, an aim hardly worthy of those whose acquirements fit them to be our leaders and our teachers, of whose reputation and fair fame we are jealous, and whose character and motives we wish to see not only without reproach, but above suspicion.

With respect to the class of authors who write for practice, it is not likely that on them any words of mine will have much influence. Were it not for the advertising columns of the daily papers, the crude and slipshod productions to which I allude would never see the light, for the parade of their authors' names is the very reason of their existence.

I remember that, many years ago, an old friend of mine, who was, I believe, sincerely anxious for my advancement, said to me, "Why don't you write a book about something? get it advertised in the papers, and keep your name constantly before the public." I replied that I had nothing to say about anything in particular which had not been already said by others much better than I could say it. I saw at once that I had fallen many degrees in his estimation, when he rejoined somewhat contemptuously, that it did not matter what I wrote or whether anybody read it—I had only to keep my name well in the front, and my success would be certain. No doubt my old friend was wise in his generation—much wiser than I was—for somehow or other that book never was written, and, on the whole, I am not sorry for it.

Now, it is a great encouragement to those who write books of this character, that they have the opportunity of introducing them to general notice in such respectable society, where they can at once flaunt it with some of the best amongst us; but if their betters could be induced to withdraw from the association, if it came to be understood that, to use a prevailing vulgarism, it was "bad form" to resort to such modes of publicity. Perhaps in time even these notifications would cease to greet the public eye, and aspirants for practice might be led to turn their energies in more legitimate directions, and at all events to make themselves masters of a subject first, and write a book about it afterwards.

I shall here venture to quote a passage from Macaulay, on the pernicious effects of puffing on the character of the general literature of his day.

"Though we have no apprehension that puffing will ever confer permanent reputation on the undeserving, we still think its influence most pernicious. Men of real merit will, if they persevere, at last reach the station to which they are entitled, and intruders will be ejected with contempt and derision. But it is no small evil that the avenues to fame should be blocked up by a swarm of noisy, pushing, elbowing pretenders, who, though they will not ultimately be able to make good their own entrance, hinder, in the meantime, those who

have a right to enter. All those who will not disgrace themselves by joining in the unseemly scuffle must expect to be at first hustled and shouldered back. Some men of talents accordingly turn away in dejection from pursuits in which success appears to bear no proportion to desert. Others employ, in self-defence, the means by which competitors far inferior to themselves appear for a time to obtain a decided advantage. There are few who have sufficient confidence in their own powers, and sufficient elevation of mind, to wait with secure and contemptuous patience, while dunce after dunce passes before them. Those who will not stoop to the baseness of the modern practice are too often discouraged. Those who stoop to it are always degraded."

Such were the words of the brilliant essayist forty-five years ago; they may seem somewhat strong in these politer times. In fact, our fathers were harder bitters than we are, but hard hitting is in no way inconsistent with fair fighting. They appear to me worth repeating now, and they are not without some application to the subject I have been discussing.

I cannot help thinking that if medical reviewers of the present day were animated by a like spirit, we should soon see changes for the better in the character and tone of our medical literature; at all events, we might hope for a great diminution in the numbers of books written. But, somehow or other, now-a-days it is only as a rare exception that one sees a medical review in which the talents and research displayed by the author are not conspicuously put forward; and if we are to depend upon reviewers, most of the medical books now published are as nearly as possible on the same dead level of superiority. I do not know how to account for this; I never wrote a book, and therefore have not been behind the scenes. I should be the last person to imagine that private influences or personal friendships had anything to do with it, because these, of course, never count for anything when it is a question of the performance of a public duty. But "a fellow feeling makes us wondrous kind"; and when almost everybody writes a book, and the reviewer of to-day will often be the reviewer of to-morrow, may not such fellow-feeling sometimes exercise an unconscious operation? Or may it be that reviewers act upon the maxim laid down, I believe, by Sydney Smith, who said it was taking an unfair advantage of an author to read his book before reviewing it, because it is so important to approach the subject with a mind perfectly free from prejudice. Anyhow, it appears to me that in the matter of reviewing, it would be a great advantage to have a little more critical discrimination, a little more separation of wheat from chaff, perhaps a little less good nature, but certainly a good deal more plain speaking.

Our profession has, I believe, a bright future in store for it, but it rests with itself whether it will use its opportunities aright. Its sphere of usefulness is expanding day by day. The great science of public and preventive medicine is only now just springing into active life. Its cultivation is an object worthy of the highest ambition, and affords ample scope for the highest order of intellect. The public is by degrees learning to look to us for the solution of some of the most intricate and important social problems of the day; and as the necessity for doing so becomes more and more manifest, so, if we prove worthy of its confidence, must the estimation in which we are held be increased.

But if our calling is to rise in the future to that high position— which, for the welfare of the community at large still more than for its own advantage, it *ought* to occupy; and which, as I believe, there are signs of the times indicating that it is sooner or later *destined* to occupy—it must be, amongst other things, through the resolute discountenance by the general body of those petty artifices by which some among us try to steal a march upon their fellows. It must be by the abandonment of individual self-seeking, at the expense of the character of that general body; it must be by the cultivation of a thorough loyalty to our order, combined always with the consciousness that the profession is for the public, and not the public for the profession. Such self-abnegation will be found in the end to be only a more enlightened self-interest, but of a kind at which no man will have a right to scoff. Still, it is only by insisting, as far as possible, on the maintenance of an elevated standard among the units, that the elevation of the mass can be secured; and each of us cannot do better than keep in mind that

"The purest treasure mortal times afford
Is spotless reputation; that away.
Men are but gilded loam, or painted clay."

THE BOSTON COTTAGE INFIRMARY will soon be completed and opened for patients. Nearly the whole of the estimated expense of the building has been subscribed; but, owing to the loss of part of it, which was paid into Messrs. Gee and Co.'s Bank, £250 is still required.

THE RELATIONS OF WOMEN TO OBSTETRIC PRACTICE.

Extract from the President's Address, delivered at the Obstetrical Society on January 6th, 1874.

By EDWARD J. TILT, M.D.,
President of the Society.

[THE first part of the President's address was mainly occupied by obituary notices of deceased Fellows and a review of the affairs of the Society. It concluded as follows.]

Independently of our work as a scientific Society, you know that we have been occasionally obliged by our metropolitan position to take the lead in questions relating to the welfare of obstetric medicine; and last year we were called upon to decide whether our laws permitted us to admit women to the fellowship of the Society. Your almost unanimous decision that women were not admissible was one of great importance; for the profession felt that, although the question was tried on a technical point, your verdict really meant that women were not qualified by nature to make good midwifery practitioners; that they were unfit to bear the physical fatigues and the mental anxieties of obstetrical practice at menstrual periods, during pregnancy and puerperality; and that it was unfair to society to encourage women to suppose that they could ever fit themselves to assume responsibility in those formidable obstetric emergencies which too often completely paralyse men of experience as midwifery practitioners. The remembrance of your decision on this question may also remind you that last year I explained to you that, in England, the lower classes of society were at the mercy of uneducated midwives, uncontrolled by aught else than the fear of a coroner's inquest. Last year, Lord Aberdeen and Mr. Stansfeld were in office; they favourably entertained the views repeatedly brought forward by the Society; and they were prepared to bring in a Bill for the better education and registration of midwives; when a change of Ministry convinced your Council that the question must be left in abeyance. It was after mature deliberation that the Obstetrical Society of London determined to move in this matter. Its original resolve has been sanctioned by successive Councils, and it will be for the new Council to decide whether it is not time to reopen the question with the new ministers. Ours is the only civilised country that has left unregulated the midwifery of the humbler classes; and it is a disgrace to obstetric medicine, that there should be no means of preventing an incompetent and drunken woman from assuming the name and the duties of a midwife. There is every probability that our efforts in this direction would be favourably received by a Government that has no great measures to carry, and which seems bent on dealing earnestly with all questions relating to public health.

Gentlemen, I cannot vacate the chair without thanking you for the invariable courtesy you have shown me in the discharge of my duty; and I likewise thank the numerous officers with whom you have associated me for having rendered easy and pleasant the duties of office. I am glad my place will be taken by one so well qualified as Dr. Priestley to preside over your meetings, to further the interests and support the honour of the Obstetrical Society of London.

REMARKS ON THE ORIGIN, VARIETIES, AND TERMINATION OF IDIOCY.*

By GEORGE W. GRABHAM, M.D.,

Resident Physician and Medical Superintendent to the Asylum for Idiots, Earlswood.

THE information which I have to give upon this subject has been somewhat hurriedly got together in the intervals of routine work. Though not sufficiently definite or extensive for the foundation of any theory, and perhaps containing little that is new, the statistics and remarks upon individual groups and cases may nevertheless prove interesting to those who have not made idiocy their special study. The time at my disposal to-day being necessarily very limited, I will at once proceed to give short definitions of the terms "idiocy", "imbecility", "cretinism", and "dementia"; and afterwards some particulars of the causes of these affections, as far as I have been able to ascertain them by inquiries in eight hundred cases.

Idiocy may be defined as "an absence or arrest of development of the intellectual and moral faculties, either congenital, or occurring in new-born children". *Imbecility* is generally taken to signify "a milder

* Read before the East Sussex District of the South-Eastern Branch.

form of idiocy, not necessarily congenital, but supervening in infancy". *Cretinism* may be termed "an endemic form of idiocy or imbecility, in which there is, moreover, characteristic arrest of development, malformation, and deformity of the whole organism". *Dementia* differs from imbecility in being "a loss, more or less complete, through disease or injury, of faculties formerly possessed". The causes of these affections may be divided under four heads:—Endemic; hereditary, or family-predisposing; parental; and accidental; any or all of which may be more or less combined. The same cause may produce effects differing with the patient's age at the time of its application: thus epilepsy will cause idiocy in early infancy; in more advanced youth, imbecility; and, later in life, dementia.

A somewhat singular fact may now be stated regarding the sex of the patients who have come under my notice. At Earlswood, the males are always twice as numerous as the females. Making every allowance for the supposition, that female idiots are more tolerable in private houses than males, and, therefore, less frequently sent to asylums, it would still appear that a large majority throughout the country are of the male sex. Nearly 65 per cent. of my eight hundred cases are stated to be congenitally defective; and, when we consider how difficult it is, even for a skilled observer, to detect idiocy in early infancy, we may feel sure that this percentage has not been overstated.

Hereditary predisposition is without doubt the chief agent in the production of mental deficiency; but it is extremely difficult to ascertain the real facts of the case, especially as it affects the upper classes of society, who appear to be almost more anxious to deceive themselves than their medical advisers on this point. Many of my patients not born with defective intellect have nevertheless inherited a predisposition which ultimately led to it. In about 18 per cent. of my cases, hereditary taint is admitted; but I am convinced that it exists in a far greater proportion of them; indeed, I have, in numerous instances, found this to be the fact from observation of the parents, or inquiries among their acquaintances. A mother, from whom I could learn no history of mental disease, and who certainly showed no indication of it in my presence, was afterwards found to be frequently moving to new lodgings, because "poison was put down the chimney into her food". In another case, I learned, after strenuous denial of any mental affection in the family, that two of the mother's sisters had been insane, and that she herself was highly hysterical. Where actual mental disease cannot be ascertained to have existed, we frequently find history of neuroses, as chorea; and often a great degree of eccentricity in one or both parents. A lady tells me, in a letter, that "her husband used to say that there was no such place as Hell; but she hopes now that he has found out his mistake".

Intemperance in the parents is even more difficult to ascertain. In six cases only of my eight hundred is it stated as the probable cause, and in two of these there was also hereditary insanity. Doubtless, *habitual* intemperance does play an important part in the production of idiocy; but I have been quite unable to assign (as has been done by my predecessor at Earlswood) any particular type of idiocy to "drunkenness during conception" as its cause. This vice is extremely common with newly married couples of the lower orders of society, whose first children are nevertheless, as a rule, at least as healthy as those of more wealthy parents.

Consanguinity of the parents accounts (partially only) for about 6 per cent. of the cases which have been admitted into the Asylum during the last six years and a half. In 11 cases only of 543, the parents were first cousins, and no other cause could be ascertained. Where hereditary predisposition coexists with marriage of consanguinity, we frequently find, as might be expected, more than one child affected. Noticing the frequency of tubercular disease as a cause of death at the Asylum, I have lately examined the papers relating to 240 cases, and find that in 55 of these, or 22 per cent., there is history of phthisis in the parents or near relatives. In 17 per cent., no other cause for the idiocy is given. Shocks or injuries to the mother, or severe anxiety while she is pregnant, are commonly supposed to act prejudicially on the child; and in many cases, in my opinion, with a high degree of probable truth. Rigid inquiry has failed to elicit any other cause in 85 out of 543 cases, or nearly 16 per cent. In many of these, the shock was a violent one; and I have an impression, not at present sufficiently confirmed by experience, that one very distinct, though small, class of the idiot is almost invariably attributable to this cause. This type usually occurs sporadically in a large and otherwise healthy family, without history of mental disease. No other cause appearing to account for these sporadic cases, we ought not to disregard the history which is forthcoming, and which I usually look for, of severe mental shock during pregnancy. As instances, I would name the bombardment of a city, a violent fall from a cart, the sudden accession of acute mania in a lady occupying the same bed, under circumstances of a pecu-

liarily distressing nature. Interwoven with this part of the subject in many ways is the fact, that nearly 23 per cent. of my cases were first-born children. Leaving the question of tedious birth for future consideration, let us bear in mind the anxiety which often precedes a first confinement, and the increased mental strain when the child is illegitimate, or has not been conceived in wedlock; also the struggle and uncertainty which newly-married couples often experience in gaining a living. The old Mosaic law was wisely conceived, which exempted the newly married for one year from labour or necessity. Tedious birth, in some cases requiring instrumental assistance, is assigned as the sole cause of idiocy in 13 cases out of 243; but probably this number is much understated. Inquiry often elicits the fact, that the child was born in a state of asphyxia, and often even laid aside for a considerable time as past recovery. Probably some severe congestion of the brain here occurs, from which it may never entirely recover; or imperfect expansion of the lungs may take place, giving rise to a cyanotic condition accompanying mental deficiency through life, but in which no malformation of the heart may exist. These cases of cyanosis are, however, by no means common. Convulsions within a few months after birth, or during the first dentition, account for nearly 20 per cent. of my cases; but it is certain, from inquiries made, that in many of these there was also some predisposing cause, the dentition exciting it only to action.

Undoubtedly, many children who were born sound become idiotic, imbecile, or demented from injuries, illness, or shocks during infancy or childhood. Including hydrocephalus supervening after birth, I find that there are about 12 per cent. who may be fairly supposed to have had their mental faculties destroyed or impaired by causes of this nature. Scarlatina, typhoid, measles, whooping-cough, severe injury to the head, being run over by a cart, ill-treatment, etc., appear in this category. A bad wet-nurse, or innutritious diet, leads to the same result in some instances.

Syphilis in the parents may account for a few cases. Information is not readily obtainable under this head; but I have seen well marked secondary syphilis in several of the children under my care.

The old age of a parent accounts for one or two cases, and premature birth for eight others. Masturbation is rarely a cause of the affections seen in an asylum for idiots. It is not uncommon, even with very young children; but is rather a symptom than a cause of their condition, which, however, it is capable of aggravating to a great degree, if unchecked. I have seen the habit cured by an occasional drop of acetum cantharidis on the prepuce in the male, and by administration of bromide of potassium in the female.

In about 27 per cent. of my whole number, no cause could be ascertained. The varieties of idiocy, using the term in a general sense, are very numerous, and run so much one into another, that it is difficult to classify them; and, as a rule, it is impossible to connect the various types with their respective causes. It may, however, prove interesting to describe the salient features of some classes, with a few remarks on diagnosis and prognosis. Idiocy, unless very marked, is not always to be recognised in early infancy. The form and size of the head alone must not be relied upon, but may furnish valuable evidence when considered in conjunction with other physical and mental signs. Some idiots have well proportioned heads, and a small head does not necessarily betoken idiocy. It is necessary to observe the way in which the infant takes and swallows nourishment; its general aspect; the flaccidity or otherwise of its muscles; its ability to raise or steady its head; to grasp the finger with its hand; its capability of noticing any passing objects, and following them with its eyes; its listening to or disregarding sounds; and the character of its voice. As life advances, the diagnosis becomes daily more easy. We compare the progress the child makes with that of other children; notice the state of the fontanelles as to closure; the form, size, and symmetry of the head; the palate, whether highly arched; the existence of any deformity; the state of the hands, as to their power of grasping; whether the fingers are thin, tapering, moist with saliva, and flaccid; the power of co-ordinating the muscles and directing the movements of the eyeballs; the circulation, whether feeble in the extremities; the presence or absence of paralysis or epilepsy; all these points will aid our diagnosis. A large proportion, nearly 130, of the inmates of the Earlswood Asylum suffer, more or less frequently, from epilepsy. This class comprises all the degrees of idiocy, imbecility, and dementia. Some are simply weak-minded, and capable of making themselves very useful; while others have lapsed into a condition of profound dementia. They vegetate rather than live, having almost no intercourse with the outer world, and little or no sensation, general or special. To this entire absence of mental wear and tear, we may perhaps attribute the fact that, though afflicted with numerous fits daily, they grow fat, and live on for many years. Epilepsy is occasionally cured; but, as a rule, these cases gradually, but

surely, deteriorate. The recurrence of the fits often annihilates all memory for recent events, entirely undoing any good which may have been acquired in their interval.

As the epileptic cases may be considered the most unpromising, so those may be deemed most capable of improvement in whom there is feeble-mindedness uncomplicated by paralysis, deformity, disease, or defective circulation; whose sensation, general and special, is normal, as also the power of co-ordinating the muscular movements.

True idiocy, unlike insanity, is invariably accompanied by other functional anomalies. Physical weakness or degeneration is constantly met with. The extremities are cold and livid, chilblains occurring, even during the warmer months, upon slight exposure. Assimilation is very imperfectly performed; the food, if not very digestible, sometimes passing almost unchanged. Diarrhoea in some is the rule rather than the exception. This defect of assimilation is seen in its most marked form in those rare cases where, in the face of a proper supply of vegetables, scorbutus occurs, and causes the destruction of one or more of the larger joints, as the knee or elbow; and, later on, the death of the patient.

A spongy and swollen state of the gums is frequently seen, also irregular decaying teeth and offensive breath. The secretions of the skin have likewise a peculiar, unpleasant odour. Undue brittleness of the bones is not uncommon. I have seen the femur and the humerus broken during the struggles caused by an epileptic fit; and I have found the long bones generally reduced to a mere shell after death. In many patients, general sensation is very low in degree, the extraction of a tooth or a toe-nail causing little or no pain. A child, who had severely burned his hand by holding it in a gas-flame, took the first opportunity after recovery to endeavour to renew an experience which to him did not appear painful. Verily, the burnt child does not always dread the fire. The special sensations are likewise affected. The taste appears to be perverted; but, perhaps, it should rather be regarded as absent, reasoning from what we know of the other senses. The organs of sight and hearing may be perfect, and yet useless: the patients see, but do not perceive. The impression formed on the optic or auditory nerve is duly transmitted to the sensorium, but no idea is thereby excited. The skin may be alike insensible to touch, heat, or cold.

A highly arched form of the palate is frequently seen in patients of weak intellect, and was attributed by Virchow to premature ossification of the sphenoido-basilar suture. The suture itself furnishes the material of ossification; so that, under ordinary circumstances, a skull-bone can only increase equally in all directions when this bone-originating suture-substance lies on all its sides. If, then, adjoining skull-bones be soldered together by premature ossification of the suture, a limit is set to further growth in that direction. If this happen to many sutures at the same time, a microcephalous skull results. If it only happen to one suture, or a part of one, an asymmetrical or deformed skull follows.

Some microcephalic patients are found to be capable of considerable improvement; one of the most marked cases of this type at Earlswood has learned to read and write, and is exceedingly useful in domestic work. On the other hand, a very unintelligent patient had a brain weighing 56½ ounces after death.

The prognosis in congenital idiocy or imbecility is, as a rule, more favourable than in those cases where it has resulted upon convulsions during infancy; yet some of our most successful cases at Earlswood belong to the latter class.

Juvenile insanity is occasionally met with, accompanied by incoherence and delusions. Sometimes lucid intervals occur, when only a certain degree of weak-mindedness is apparent. These are unfavourable cases. Delusions are very rare in an idiot asylum, indicating, not absence, but perversion of intellect. Moral insanity, accompanying weak intellect, is more common. Patients affected with this variety of disorder are, perhaps, the most troublesome ones with whom we have to deal. The mischief and destruction wrought by them is almost incredible. Sometimes they have a very intelligent look; and they certainly know right from wrong, as they invariably choose the latter. They are cunning in the extreme, and evidently fear detection, though punishment would have no effect in correcting their perverse nature. Improvement to any great extent does not often occur in this class.

Another variety appears very promising, but causes much disappointment. It consists of bright, vivacious, intelligent-looking children, from whom much might be expected; but they are taught with extreme difficulty, appearing to lack the power of concentrating the attention upon any subject.

A rare class consists of sporadic cretins: stunted beings, with pale or discoloured skin, highly arched palate, deformed head, and tumid abdomen. These have been supposed by Dr. Fagge to have no thyroid gland; but this supposition has been proved to be incorrect by the occurrence of bronchocele in a typical instance under my care. Dr.

Down read a paper on a case apparently of this type, which he attributed to drunkenness during conception.

Another very distinct class has many features in common with these last; but its members are much more improvable, though they seldom get beyond a certain stage. This type I hope to make the subject of a special paper. The Asylum contains a few patients who are affected with involuntary movements simulating chorea, but arising from a defect of co-ordinative power, which is, as far as I have been able to learn, congenital. The involuntary movements are remediable to some extent; but usually persist more or less through life. The mental faculties, on the other hand, may materially improve; indeed, it is wonderful to see what some of these patients can do with their hands, in spite of their infirmity.

A curious class may be termed that of the idiot "savans", in whom one or more faculties are amazingly developed, perhaps to the detriment of the rest. One has a marvellous power of acquiring languages and musical knowledge; another, great mechanical skill and original constructive ability; a third, though very childish, is no mean mental arithmetician; a fourth remembers all he reads; a fifth delights in dates; while a sixth can tell the time when awakened from sleep. General improvement has taken place in all these cases.

Dr. Seguin, a well known authority on idiocy, has given the support of his pen to a theory "that idiocy is found in its simplest forms among the labouring classes, and that, among the wealthier classes, it is not only oftener aggravated by accessory diseases, but also complicated with abnormal semi-capacities or disordered instincts, which produce heterogeneous types to an almost unlimited extent. It is from this class almost exclusively that we have musical, mathematical, architectural, and other varieties of the idiot savant; useless protrusion of a single faculty, accompanied by a woeful general impotence". I am quite unable to agree with this view; my experience of many of these idiot "savans" proving them to have sprung from parents in humble circumstances, and leading me to believe them to have resulted in many instances from hereditary insanity.

Permanent deafness and dumbness often accompany weak intellect, but do not prevent improvement under proper training. Some have even to some extent acquired the art of lip-reading. As to the general results of training, Dr. Seguin says with truth that "some have made more or less rapid progress, and qualified for different grades of manhood. Some present meliorations, which could not have taken place without the training, though they are mostly attributable to growth, increased strength, automatic habits, and unavoidable surroundings. Some are decidedly as idiotic as ever. Some actually retrograde, either by an *ab initio* falling off, or since a certain date, event, or sickness; or by the effects of that young senility of which idiots give the curious and, as I believe, unique example."

The diseases of idiots are of an asthenic type; they have little power of resisting any acute disease. Phthisis is frequent among them, often running a rapid course in a few weeks, unaccompanied by cough or expectoration. Too much importance has been attached to certain critical periods, when some sudden improvement is not uncommonly anticipated by the friends of the patient. I have witnessed no facts supporting these expectations. The age of puberty is undoubtedly a critical time with idiots; degeneration often commences then, and deaths are frequent; but I have not seen improvement suddenly commencing at this period. Those who survive it frequently remain without sexual development, and sometimes, in the case of females, great obesity supervenes.

The death-rate at Earlswood has been very low during the last six years and a half, no death having occurred from epidemic or infectious disease, which in former times has occasionally been very fatal. In this period, 160 deaths have taken place, at the average age of 17.6 years, from the following causes.

Tubercle in Brain or Membranes ..	3	Tubercular Peritonitis	2
Cerebral Disease, Softening, etc. ..	6	Inflammation or Ulceration of	
Meningitis	7	Bowels	5
Epilepsy	38	Diarrhoea	2
Phthisis Pulmonalis	59	Hepatic Disease	2
Bronchitis and Pneumonia	9	Renal Disease	6
Disease of Heart	2	Cancer of Ovary	1
Juvenile Senility	7	Caries of Vertebra	1
Tubes Mesenterica	6	Disease of Knee or Shoulder-joint	3

Thus 72 deaths are recorded from scrofulous diseases, ascertained to have existed, and 38 from epilepsy and its results. Many of the epileptics, moreover, had tubercular deposits in the lungs at the time of their death. Upon the other causes, it may be remarked that diarrhoea is frequent with idiots, and inflammation of the mucous coat of the intestines not uncommon, occasionally running into ulceration and perforation. The heading Cerebral Disease includes one or two cases in which a *post mortem* examination was not made, so that its precise

nature was not ascertained. Tubercle in the brain-substance occurred in one case. There were several hard masses as large as a filbert in the white matter of the hemispheres, while the corpus dentatum of the cerebellum was almost entirely supplanted by a hard scirrhous-looking mass, through which nerve-fibres appeared to pass. Doubting the nature of this product, I submitted it to Dr. Lockhart Clarke, who kindly examined it, and pronounced it to be tubercle. The child in whose brain this deposit occurred will doubtless be remembered by some of the members of this Branch, as having been pointed out to them when they visited the Asylum. He had never learned to walk, seldom used his hands, though they were by no means powerless; but could make wonderful use of his feet, with which he would throw or catch a small cushion, hold a biscuit while eating it, rub his eyes, or scratch his head. The movements of the eyeballs were imperfectly controlled, but this was the only apparent defect of co-ordinative power. The child died very suddenly, without any previous illness. A case of disease of the knee-joint and another of the shoulder-joint were originally due to a severe attack of scorbutus, the former surviving three years, and the latter about three weeks.

One of the cases of caries of the vertebrae was interesting, from the fact, that, though dislocation of the axis and atlas actually occurred, death did not immediately result from it. The nature of the disease was suspected some time before death, and the patient very carefully attended to in bed. The actual cause of death was intense inflammation of the membranes, consequent upon the entrance of pus into the cranium through the foramen magnum.

The term Juvenile Senility is the only appropriate one with which I am acquainted for describing a not uncommon cause of death in idiots. An undeveloped child (perhaps I ought to say "man", for he was 22 years of age, though only 2 feet 4 inches high), suddenly began to fail in spirits and in appetite. His circulation became gradually more feeble, and his temperature fell, until his extremities were perfectly cold. Death resulted in a few days, and a *post mortem* examination revealed no disease.

THE DETERMINATION OF REFRACTION OF THE EYE.

By W. LAIDLAW PURVES, M.D.

EVERY one who has to determine the refraction of numerous patients, knows the trouble and labour involved in finding the number of lens in the test-box, cleaning the lens when found, placing it in a proper position before the eye of the patient, and replacing it in its proper slit in the box. When to these are added, in the case of patients with astigmatism, the placing of the axes of the cylindrical lenses always in the already determined meridian, no one is able satisfactorily to order glasses in the usual hours of a *clinique* for half the cases of astigmatism which present themselves at any large ophthalmic hospital. I believe that half an hour is about the limit which should be given to a case at a visit. Though the surgeon may not have tired of observing, the patient is generally by that time in a condition in which his answers cannot be well relied on; and, if the surgeon have not by that time satisfied himself of the lens necessary, it is better to hold by the observations already made, and add to them on a future occasion. Any means which will set aside the difficulties above mentioned, and at the same time determine the refraction with accuracy equal to the means already used, will prove of use both to patient and to surgeon; and it is on this account I have had the following instruments constructed.

In two discs revolving from their centres, and placed on a telescopic stand, are cut thirteen apertures, in twelve of which are fixed twelve plano-convex and twelve plano-concave spherical lenses; the discs containing the one kind of lenses revolving, so that any number of lens in that disc can be brought against any lens in the discs containing the opposite kind of lens, as in the ophthalmoscope I proposed in the beginning of 1873. The two remaining apertures are left vacant. By these means, numerous powers are obtained, which will be found especially useful in cases of high degrees of ametropia.

The glasses placed in the discs are as follows: + and - 2, 3, 4, 5, 6, 8, 10, 13, 18, 24, 36, and 48; and by these are obtained the following + or - powers; viz., 2, 2.08, 2.11, 2.18, 2.25, 2.36, 2.5, 2.66, 3, 3.2, 3.27, 3.33, 3.42, 3.6, 3.9, 4, 4.28, 4.36, 4.5, 4.8, 5, 5.14, 5.58, 5.77, 5.80, 6, 6.31, 6.66, 6.85, 6.92, 7.2, 7.5, 8, 8.12, 9, 9.6, 10, 10.28, 11.14, 12, 12.63, 13, 13.33, 13.84, 14.4, 15, 17.14, 17.82, 18, 20, 20.8, 20.34, 22.5, 24, 28.36, 28.8, 30, 36, 40, 43.33, 46.8, 48, 72, 144. Each of these is engraved on one disc, and seen through aper-

tures made in the other disc; but, should there not be sufficient to satisfy the demands of some, the enlarging of the discs and the substitution of other or more glasses is easy.

For the determination of astigmatic cases, the same method of revolving convex over concave cylindrical lenses, or *vice versa*, is used; the placing of the axes in the different meridians being obtained by the same method as in Javal's optometer, or by causing the patient to look through the aperture in the disc corresponding to the meridian of his astigmatism. The two discs are so constructed as to revolve round a graduated circle external to their peripheries, so that any glass is brought before the eye with its axis in any desired meridian; while, being at the same time able to revolve upon a central axis, any single glass or single combination of glasses in the discs may be used as in the discs containing the spherical lenses. The cylindrical glasses used are as follows: 5, 6, 8, 12, 36, and 48 + and - , by which the following powers of each kind are obtained; viz., 5, 5.58, 5.80, 6, 6.85, 7.2, 8, 8.57, 9.6, 10.28, 12, 13.33, 16, 18, 24, 30, 36, 48, 144.

The two instruments may be used separately or together.

For the purpose of controlling the patient's accuracy of observation for the different meridians, I use a disc with varied numbers of lines engraved in different meridians, by the revolving of which one can determine whether the patient sees accurately in any meridian by his counting correctly the number of lines placed in that meridian. I have had lines and letters similar to Pray's cut out in metal, and so placed against a light that patients in whom the circles of diffusion are abolished sufficiently by lenses, can recognise the number of lines or the letters used; but I find the above described method the simplest.

As the calculation of fractions is a trouble to some, I have had a boxwood scale made, which will suffice for calculating the fractions on the ophthalmoscope and optometer, the latter of which would be considerably lessened in price by the using of the card instead of the engraving and boring of the discs necessary to show the combinations.

This optometer fulfils, I believe, all the requirements necessary in determining cases of ametropia, in that by it we can determine at the same time the condition and degree of refraction and the acuteness of vision, the latter of which has, in the optometers of Young, Lawrence, Burrow, Graefe, Javal, etc., to be determined as a second step, and all artificial values are done away with.

I trust that, by thus simplifying the determination of ametropic cases, general practitioners may be induced to give more attention than hitherto to the relief and prevention of the numerous and varied consequences which the non-use of glasses in ametropes often entails.

MICROSCOPICAL EXAMINATION OF THE SPUTUM IN PHTHISIS.*

By JAMES SAWYER, M.D.Lond., M.R.C.P.,
Physician to the Queen's and Children's Hospitals, Birmingham.

I DESIRE to say a few words upon the method and value of a microscopical examination of the sputum in phthisis. During several years, I have been in the habit of occasionally using the microscope in the examination of pulmonary expectoration. In some cases of chronic phthisis, such a procedure may sometimes give information which no other mode of research can furnish. It is not necessary for my present purpose that I should enter into a discussion of the pathology of consumption of the lungs. My remarks concerning sputum apply to cases of ordinary chronic phthisis. The term "phthisis" has now become generic; it includes several varieties of pathological change, the discrimination of which is of the highest practical importance. But all my hearers—whether, with Laennec and many others, they believe in the existence in the lungs in phthisis of crude lumps of yellow tubercle; whether, with Niemeyer, they hold such masses to be simply inflammatory products which have undergone a cheesy metamorphosis; or whether, following the example of many English pathologists, they take that middle course which is usually held to be the safest—whatever be their own views on a subject which is certainly at present far from clearly worked out, my hearers all know what I mean when I speak of the ordinary form of chronic pulmonary phthisis. I mean the commonest kind of consumption. I mean the commonest of all diseases of the lungs. I mean a disorder which runs a chronic course, and is characterised by the extensive and extending solidification, softening, and excavation of circumscribed portions of pulmonary tissue.

So far as I remember, my attention was first drawn to the importance

* Read before a meeting of the Microscopical Section of the Birmingham and Midland Counties Branch.

of a microscopic examination of the sputum in some cases of phthisis by a paper from the pen of Dr. Fenwick, which appeared in one of the medical journals in 1868. The method of procedure therein advised I have frequently found in practice to be most satisfactory in its results. If we compress a portion of phthisical sputum on a slide, we can readily see, with a quarter-inch, epithelial cells from all parts of the respiratory passages, mucus and pus-corpuscles, blood-discs, "exudation-corpuscles", etc. But such a plan will not very readily bring into view minute portions of pulmonary tissue, and these are the characteristic marks of destruction of lung-tissue. Dr. Hughes Bennett was the first, so far as I am aware, to make the discovery of elastic tissue from the lungs in the expectoration of consumptives. Mainly following Dr. Fenwick, I have found it best to slowly boil about two drachms of the sputum to be examined in a test-tube with an equal quantity of the solution of caustic soda. The alkali soon destroys the ropiness of the expectorated matter, and reduces the mixture to the limpidity of urine. Mucus and pus-corpuscles are disintegrated, and fragments of less easily destroyed tissue, such as minute portions of lung-tissue, fall to the bottom of the tube, and may be conveniently removed by a pipette and placed upon a slide for examination. We may find the beautifully slender and curling fibrils of the yellow elastic tissue of the lungs, or scraps of the smallest bronchial tubes, or shreds of the outlines of groups of air-cells. I have rarely seen more attractive microscopic objects than those afforded by phthisical sputa. I have seen in the field at once the outlines of half-a-dozen groups of air-cells as clearly marked as in a diagram, with here and there the traces of red blood-cells, and scattered amongst all, what is a very common object in these cases, minute portions of coal, or other hard, black, and insoluble material.

In many cases of phthisis, there is no need, at least for purposes purely diagnostic, to go to the trouble of making a microscopic examination of the sputum. But, even when the physical and other signs are so unequivocal as to leave no room for doubt as to the nature of the disorder, the discovery of fragments of pulmonary texture in the expectoration will furnish very interesting confirmatory evidence as to the condition of the patient. But do we not all of us sometimes meet with early cases of consumption, in which, though suspecting the malady, and even after frequent and very close investigation of the facts before us, we still remain in doubt as to the actual existence of phthisis? For the further elucidation of such cases, I would suggest the careful microscopical examination of the sputum. The discovery of shreds and fibres of the tissue of the lungs will indisputably demonstrate the results of the breaking down of pulmonary texture. When we are hesitating as to a conclusion, a grain of new fact is worth a bushel of speculation.

MALARIA: REJOINDER TO DR. MACLEAN.

By T. INMAN, M.D.,

Late Lecturer on Medicine at the Liverpool Royal Infirmary School of Medicine; Consulting Physician of the Liverpool Royal Infirmary.

IT certainly is not requisite for a man to have visited Hindostan and China, Ceylon and Sierra Leone, to understand whether an author who writes upon those parts is logical in the conclusions which he draws from his facts. Experience has also abundantly proved that travellers who stay at home, read, and think, know more than those whose pen simply reflects what the eye sees and the ears listen to.

Dr. Maclean is aware, he tells us, that paroxysmal fevers occur in ships at sea; and attributes it to bilge-water. I can tell him that his theory is valueless, for the folks attacked are not those who sleep between decks, but those who sleep in the open air; and that the use of an awning, or even a good blanket, will prevent the spread of the fever, the bilge-water remaining the same. Again, the bilge-water being a nearly constant quantity in ships, it follows that, if it be the cause of fevers, ships must be as bad as marshes, especially when sailing before the wind and almost incapable of being ventilated. But fevers at sea are rare, and are determined by heavy work on a hot day and sleeping on deck during a starlight night. I have not, in the course of my reading, found out that any maritime population sleep in the open air when hot with work in tropical climates. The immunity from fever which Dr. Maclean claims for such, I should say was due to the good sense which has taught them to sleep under shelter.

In Dr. Maclean's fourth paragraph, he allows that ague may arise in rocky districts, where there is little or no vegetation; and then talks vaguely about rotten granite, fungi, water below the surface, old wells, etc. This again reminds me of Tenterden steeple and the Goodwin sands. Why, there is not to be found a spot on the earth's surface where water cannot be found by those who dig for it. Consequently, if

water be the cause of ague, the disease ought to be universal; and, if rotten granite and fungi be a cause of paroxysmal fevers, those affections ought to be found largely in Cornwall, where there are vast moors covered therewith.

But Dr. Maclean not only attributes disease to impossible causes; he ignores those which are known to be in common, almost constant operation—viz., the relative heat of day and night, when a person is necessarily exposed to both without shelter. The worst place for ague which is known in the world are certain black basaltic rocks—I think on the Rio Negro, in Peru. Few parties encamping on them at night escape. Here, however, there is no rotten granite, no fungi, no water near the surface, no soil, no bilge-water, no old wells, etc. Whence, then, comes the fever? In replying to the question, after ascertaining the truth of the "facts", the careful inquirer endeavours to discover what there is in common between this locality and the Pontine marshes, the Maremma, the sandy shores of Walcheren, the parched wastes near the Douro, so fatal in the Peninsular war. He compares these arid rocks with those of Aden; with the sandy Sahara; the deadly rivers in India, Burmah, and Africa; with the swamps of Florida and below New Orleans; with trenches newly dug; and with ships at sea having stinking hides or bilge-water aboard. It is this inquiry which a physician can make in his study, quite as well as a regimental surgeon who knows fever at Hong Kong, but not at Sierra Leone or Gambia. I most unquestionably do not feel a high respect for those who attribute effects to what seem to me to be inadequate if not absurd causes; but I do not intentionally use a sneer in lieu of an argument. Let me for a moment refer to a matter mentioned by Drs. Maclean and Tilt, who attribute certain cases of fever to the formation of excavations for drains and the emanations consequent thereupon. "Fever comes from digging holes", is the proposition. Well, suppose it does: then fever must have been common at the sieges of Sebastopol, Seringapatam, Burtপুর, Paris, Badajoz, Vicksburg, etc.: it ought to have followed the "navvies" along every one of the railways which exist in Europe. There is not an acre, which has been drained deeply, which ought not to have produced its paroxysmal fever; there is not a well-sewered town the course of whose deep drains must not have been mapped out by fever, or a canal whose makers have not been scourged with agues or remittents. The new Suez Canal, with its saline lakes, its salt marshes, and deep-seated water, ought to have caused the death of myriads; and ploughing and delving on the Maremma ought still to be a fearfully fatal occupation. Is any one of these things so? Does sewerage produce ague—here or in France? If not, surely it is provocative of a smile to see a single accidental case of fever, occurring in a street containing probably five hundred to a thousand inhabitants, attributed to the formation of a drain; and when this bit of reasoning is ushered in by a sneer at the author of inductive reasoning, and by a reference to some glacial theory of the class, *risum tenetis amici*? Equally curious it is to see that coffee-planters at Ceylon are used to support the digging theory hatched at Hong Kong. If trenching could produce agues, the troops at Chatham and labourers at the fortifications about Portsmouth ought to be very unhealthy; and this they are not. Again—to use some more inductive reasoning—let me ask why labourers who used to plough, trench, dig, and excavate in the Fen country and on the Italian marshes were once as subject to ague as the coffee-planters in Ceylon? why those who so delve in England are now free? Is it not certain that there is, or was, a cause in Italy and Ceylon which is not now in existence at home? In all cases, there are soil, water, excavating; nor can the keenest observer find a distinction in the ground thus disturbed. The cause is patent to a close observer, but I need not dwell upon it. I have, without going to Netley, seen men with the stamp of ague on them—some in the de-l-house of the Liverpool Royal Infirmary, many more in the wards of that institution, and still more in Southern Italy; but seeing ague-patients alone does not give us information about the agent that worked the mischief. But I have also had—what I shall not find at Netley—the benefit of the experience gained by a civil engineer who has long had to do with fevers occurring in a set of African steamships which trade also to American ports, all notoriously "malarial". The loss and injury to health amongst the men employed was extremely serious, and my friend endeavoured to diminish the unhealthiness. He succeeded. Without knowing even of the existence of Dr. Oldham, he traced the fevers to the same cause as the doctor does; and, by insisting that all who sleep on deck shall put over them a light awning made for the purpose, and thus prevent chill by radiation, the ships under his eye are free, or nearly so, from "malarious" disease.

As I notice that Dr. Maclean does not support his emanation theory by proving that agues are caught by day, when emanation is lively, nor by insisting that emanations are most active when air, heavy with dew, is slowly falling to the ground, and as he acknowledges that, even in

England, chills after exertion in a heated atmosphere may produce some of our most formidable acute disease, I will not make further remarks upon emanation *versus* chill.

ALCOHOL AS A MEDICINE.

By WILLIAM BERRY, M.R.C.S. Eng., L.R.C.P. & S. Ed.

THE interesting papers of Drs. Russell and Sutherland on Alcoholism, as well as the paper of Mr. Lucas, in the JOURNAL of November 14th, will be read by many with the interest and attention they deserve. These admirable papers will cause members of our profession to pause before prescribing alcohol as a remedial agent, especially for women and children, and, to the more inquiring, will cause them to ask themselves what other remedy they can employ instead with equal benefit to the patient. I, for one, do not believe that medical men, as has been asserted, are answerable for the moral degradation of the people from drunkenness, through their indiscriminate prescriptions, but believe, on the other hand, that they are capable of wielding a mighty power against its spread whenever they see a tendency to the development of that habit we call dipsomania.

I am pleased to see that this subject is demanding the attention of eminent members of our profession, that legislation is likely ere long to deal with the subject, and to provide some means of treating this form of mental weakness. That alcohol is a valuable therapeutical agent cannot be denied; and that it has stimulant and narcotic properties, according to the dose, is equally certain, although Mr. Lucas is pleased to term its narcotic effect over-stimulation.

In acute febrile diseases, we see marked benefit derived from its moderate and judicious employment, and have little fear of setting up the habit of its continual employment, if we reduce the dose while the patient is convalescing. It is in nervous people, especially women suffering from neuralgias, faintness, or nervous depression, that we require to be more guarded, and, if possible, to employ a substitute. In these cases, as in all others, the medical man should be definite in his prescription, and should never prescribe it *ad libitum*, but order a certain quantity every three, four, or six hours, or as often as he thinks it requisite; and, as soon as improvement is noticed, he should diminish the dose, finally substituting a nerve tonic in its stead. It is also a good plan to order a biscuit or a small quantity of food to be taken with the stimulant.

Mr. Lucas has arrived at erroneous conclusions from the experiments he has made, when he denies the narcotic effect of alcohol. He admits that alcohol does not pass unchanged out of the body, but is largely oxidised; and he says also that it is to the result of this oxidation that we have its narcotic properties. He believes, moreover, that it is a *pure stimulant*. In large doses, he says, it stimulates to death, giving as an example a person having drunk a quart of rum or brandy falling down dead from over-stimulation, dying from exhaustion of nerve-force; but is it not more likely to be from paralysis of the nerve-centres? The person does not show any signs of stimulation, excepting such as we see in narcotism from other drugs. Opium, for instance, is a narcotic poison, but in small doses it is a powerful stimulant; surely, then, we should not say, in a case of poisoning by opium, that it had stimulated to death.

In admitting that death from a large quantity of alcohol is due to exhaustion of nerve-force from over-stimulation, we must believe that nerve force is capable of expending itself, after the manner of gunpowder when a lighted fusee has been applied. That its narcotic effects cannot always be explained by its decomposition into carbonic acid and other impurities, thereby charging the blood with the same, is equally certain, and is disproved by the case of the toper who becomes suddenly narcotised after a large dose, and before the blood could possibly become charged with the results of its decomposition. That in cases of drunkenness, the stupor and sleepiness may be theoretically explained in this way, I am not prepared to deny. The effect of alcohol stimulating the animal passions needs no comment. In medicine, it is never used for such a purpose; therefore, this question does not affect us as practitioners. Moral men, of course, ought to keep within bounds, or be total abstinents.

Mr. Lucas also questions the theory of alcohol preventing waste. Dr. Parkes found that urea was not diminished by the use of alcohol in the healthy adult; but the late Dr. Anstie found that the quantity of urea was considerably diminished by its use in a case of typhus. Now, if this were really accumulating in the blood, as Mr. Lucas suggests, its formation not being prevented, we should have uremia in its worst form; but is such the case in fever-cases, in which large quantities are taken to sustain life? Its action on the albuminous tissues, as shown

by Dr. Ross, and also by Dr. Beale, will explain how it prevents the formation of urea, thus diminishing its excretion when the quantity is large.

To my mind, Mr. Lucas totally fails to show that alcohol is not an useful and suitable medicine when properly employed; neither has he suggested any other remedy in its stead. We have depressing effects after the use of any stimulant, unless its effects be kept up, either by repetition or an equivalent in the form of food or another stimulant substituted; but, in treating diseases which require stimulation, the convalescence of the patient removes all demand for the remedy. It does not matter whether we administer alcohol in shape of spirits of wine, brandy, or wine; but it is well to have a choice, as no one form is suitable for all cases. I have seen drachm doses of spirits of wine, coloured with cochineal, and taken every four hours, produce beneficial results, when the same amount of brandy would have been refused on moral grounds.

How far alcoholic stimulants are necessary to healthy people, either taken with food as an article of diet, or at bed-time as a night-cap, I am not prepared to say. Its habitual use, even in moderation, and that of tobacco, which is also held to be unnecessary, form subjects for the moralist to discuss, and do not affect us as physicians, or its use as a medicine.

REPORTS

MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

GREAT NORTHERN HOSPITAL.

A CASE OF INJURY TO THE FACE, PRODUCING DEFORMITY OF THE FEATURES: THE DISTORTION IN PART REMEDIED BY PLASTIC OPERATIONS.

(Under the care of Mr. W. SPENCER WATSON.)

JAMES C., aged 25, was kicked in the face by a horse, ten years ago. While training the horse, by whipping it round in a circle with a long leading-rein, the animal suddenly backed on him and kicked him violently in the face. He was knocked down, and when picked up the left side of his face was, as he described it, lying on his left shoulder. There was still evidence that both jaws must have sustained compound comminuted fractures; the nose was split open nearly vertically, and the anterior wall of the antrum broken into through the integuments of the cheek. The contraction of the cicatrices formed during the healing of these injuries, resulted in a drawing down of both the left eyelids to a point above the middle of the inner side of the nose, so that the patient was unable to open his left eye by any movement of the muscles attached to the eyelids, though when the palpebral aperture was dilated by the fingers, the eyeball was seen to be perfect, and the sight of the eye itself was unimpaired. The jaws were much distorted, and could only be opened to a limited extent. Nevertheless, mastication and articulation could be very fairly performed. In the middle of the left cheek was an opening communicating with the antrum, and the skin surrounding this opening was drawn down towards it in the form of a funnel-shaped depression.

The above description applies to the condition of the patient when he was admitted into the Great Northern Hospital, in July 1874, for the purpose of having an operation performed, designed to restore binocular vision.

Having several times successfully operated for ptosis, by removing portions of the upper eyelid, and so bringing the eyelid within reach of the fibres of the occipito-frontalis, Mr. Watson proposed a series of plastic operations in which this principle might be rendered available.

On July 16th, chloroform having been administered, a flap was taken from the upper eyelid, of a somewhat elongated oval form, and inserted in a raw surface left by making a free incision below the lower eyelid, dissecting the skin upwards, and freeing it by making deep cuts into the hard fibrous cicatricial tissue, by which it was bound down to the upper jaw. The edges of the wound in the upper lid were then brought together, and the flap retained in its new position below the lower lid by sutures. The whole of the parts operated on were then covered by a layer of cotton-wool saturated with styptic colloid. In this operation, care was taken to dissect up the lacrymal sac with the inner end of the eyelids. An attempt was made to draw up the flap thus formed, without dividing the lower end of the sac and the commencement of the nasal duct, but this was found to be impossible; the lower end of the sac was, therefore, cut across, and the divided

ends separated in the act of drawing the eyelids into their new position. Notwithstanding that a portion of the transposed flap underwent considerable shrinking, and partially sloughed, the ultimate effect of this operation was a decided gain. The inner canthus was raised half an inch higher than the outer, which was before the higher of the two; and there was a slight power of raising the upper lid, so that the patient could see before him when he held his head up and threw it back slightly.

It was, however, necessary to raise the outer canthus; and, in order to do this, on August 26th, an operation of a precisely similar kind was performed at the outer side of the eye, the flap being taken from the skin and subcutaneous tissues, including muscle, of the outer half of the upper eyelid, and this flap transposed to a gap made by a horizontal incision below the outer two-thirds of the lower lid. Styptic colloid was applied to these incisions as in the former operation. The result of this operation was to increase very considerably the power of opening the eyelid, the level of the palpebral aperture also being very much raised; but the outer half of the upper eyelid remained everted slightly, and this unsightly effect was subsequently remedied by removing the protruding portion of the conjunctiva, and a small piece of the tarsal cartilage.

On October 14th, the following operation was performed, for the closure of the antral fistula, which lay at about the middle of the cheek, in a hollow, close to the side of the nose. Three flaps were taken from the skin of this hollow, by dissecting them from the central aperture outwards; the two lowermost flaps were then brought together by quilled sutures, so that their deep surfaces were in contact, in the form of a raised eminence, over the site of the depression, and the uppermost flap was attached to a point above them near the root of the nose, its lower edge being also attached by sutures to the upper borders of the two lower flaps. Styptic colloid was then applied in the way usually employed at the Great Northern Hospital.

On the fifth day after this operation, the crust of colloid fell off, and the flaps were seen to be in good position, and in great part united by primary union. On the fifteenth day, the wounds had become completely healed, and no trace of the fistula remained. A prominent nodule of redundant skin marked the union of the two lower flaps by the quilled suture. On November 1st, there being still an insufficient power of raising the upper eyelid, the following further operation was performed.

1. The prominent fold of mucous membrane projecting from the outer half of the upper lid, and a portion of the cartilage, were removed, the cut edges being brought together by sutures. 2. A portion of the skin of the upper lid, between the inner canthus and the inner extremity of the eyebrow was dissected off. The edges of this raw surface were brought together by sutures. The object of this operation was to diminish the extent of the skin of the upper lid at this part, and so bring it within reach of the fibres of the occipito-frontalis. The piece of skin removed was about the size of a shilling, but triangular in shape, the base of the triangle being outwards. At the same sitting, Mr. Watson removed the prominent nodule on the cheek by means of the toothed scissors. On November 17th, the wound had healed, and there was decidedly more power of uncovering the cornea; but the inner end of the eyelid was slightly everted, and the patient expressed himself as anxious to have this remedied.

To effect this, it was clearly desirable, first, to remove the everted conjunctiva which overlapped the cornea and the pupil at the inner third of the palpebral aperture, this being caused by the undue eversion of the upper tarsal cartilage; and, secondly, to reduce the length of the upper tarsal margin, and bring its inner end more towards the root of the nose. By this means, it was anticipated that the cornea would be more readily uncovered, and the aspect of the patient much improved. Accordingly, on November 26th, the inner fifth of the margin of the upper eyelid was removed with the eyelash, and with a V-shaped portion of the cartilage. A raw edge was thus left, just external to the upper punctum lacrymale. From the inner extremity of this, an incision was carried obliquely upwards and inwards, and a triangular piece of skin removed immediately below the inner extremity of the eyebrow. The raw edge of the tarsal margin was then attached by wire sutures to the upper and inner angle of the triangular surface, and the margin of the lid was thus considerably shortened. Sutures were placed in the adjacent edges of the flaps, and the whole covered with cotton-wool and styptic colloid. On December 15th, the wounds had quite united, and the tarsus maintained its new position, giving a more free aperture for seeing purposes, though it was still difficult for the patient to see directly upwards with the left eye. A slight eversion of the outer half of the conjunctival surface remained, and was very unsightly; but this may possibly be remedied by the application of mineral astringents.

GENERAL HOSPITAL, BIRMINGHAM.

FRACTURES AND DISLOCATIONS TREATED DURING THE THREE WEEKS DECEMBER 14TH TO JANUARY 2ND.

[Reported by WALTER OTTLEY, M.B.]

THE number of fractures that occurred in Birmingham during the late frosty weather having been unusually large, I felt that it might be of interest to draw up a table of those attended to at this hospital during the last three weeks. The majority of them could be traced to the slippery state of the pavements. In the case of compound fracture of both legs, amputation through the upper third of each leg was performed by Messrs. Goodall and Jolly simultaneously. The patient has since done remarkably well. The following is the list.

Fracture of femur ...	13
Fracture of tibia and fibula ...	10
Fracture of tibia ...	3
Fracture of fibula ...	25
Fracture of patella ...	1
Fracture of base of skull ...	1
Fracture of inferior maxilla ...	1
Fracture of ribs ...	18
Fracture of coccyx ...	1
Fracture of humerus ...	4
Fracture of radius and ulna ...	6
Fracture of radius ...	7
Fracture of ulna ...	1
Fracture of olecranon ...	1
Colles' fracture ...	41
Fracture of metacarpal bones ...	6
Fracture of clavicle ...	5
Compound fracture of femur and leg ...	1
Compound fracture of both legs ...	1
Compound fracture of tibia and fibula ...	1
Compound dislocation of ankle and fracture of pelvis ...	1
Dislocation of humerus ...	7
Dislocation of finger ...	2
Dislocation of clavicle ...	2
Dislocation of elbow ...	1
Total ...	160

REVIEWS AND NOTICES.

COMPENDIUM DER NEUEN MEDICINISCHEN WISSENSCHAFTEN. ENTHALTEND: 1. Thermometrie. 2. Sphygmographie, etc. Von Aerzte, Lehrende, und Lernende nach dem gegenwärtigen Stande der Wissenschaft fasslich, die Materien erschöpfend. Dargestellt unter Mitwirkung hervorragender Fachgelehrten, von Dr. BERNARD KRAUS, Chef-Rédacteur der *Allgemeinen Wiener Medicinischen Zeitung*, etc. Wien, 1875. Moritz Perles. [Mit 71 in dem Text gedruckten bildlichen Tafeln].

AN EPITOME OF THE SCIENCES ACCESSORY TO MODERN MEDICINE, including Thermometry, Percussion and Auscultation, the use of the Ophthalmoscope, Laryngoscope, Sphygmograph, and Microscope. Anomalies of Speech, Aural Surgery, the Examination of Urine. Electro-Therapeutics, Hygiene, and Toxicology: for the use of Medical Men, Teachers, and Students. Edited by Dr. BERNARD KRAUS, assisted by eminent Professors. Pages 852, with upwards of 70 figures. Moritz Perles. Vienna, 1875.

HERE and there one meets, even in the most distant colonies, with men who make themselves familiar with all the advances of medical science. These are the men who furnish us with new tests for blood, and fresh disinfectants from Australia; contribute to our knowledge of helminthology from the frigid shores of Iceland; or write manuals of ophthalmic surgery and medical jurisprudence beneath the burning sun of India. It must be confessed, however, that such men are rare, and it can scarcely surprise us to find that they are so. In the last half century, a number of new instruments have been pressed into the service of modern medicine, and the use of old ones, such as the thermometer, has been revived. The crude guesses of the old water-doctor have been changed by methods of precision into matters of certainty. The microscope and chemical tests reveal fragments of expectorated lung-tissue before even Laennec or Louis could detect pulmonary mischief by the most careful auscultation or percussion; and the ophthalmoscope gives warnings of grave cerebral disease before the patient complains of either his sight or his sensations. But, alas, the literature

of these new processes and new discoveries is not only voluminous enough to need a new Atlas to carry it, but is scattered through hundreds of periodicals and volumes. Even when the practitioner knows where to find what he wants, it is often difficult for him to find the time required for its perusal; and then again, many of the desiderated treasures are in a foreign tongue, which he does not read at all, or reads with difficulty.

Obvious considerations of this kind, and twenty years' editorial experience in conducting a well-known Vienna medical newspaper, have convinced Dr. BERNARD KRAUS of the absolute necessity for a volume of this kind; nay, to show still farther how popular such a book is likely to be, we understand that an eminent publishing firm are already making arrangements for an English edition of the volume before us. Making allowance for some personal peculiarities (which culminate in an amusing paragraph denouncing English microscope-makers), we think Dr. Kraus, as might be expected from his trained pen, has done his share of the work exceedingly well. The same cannot be said for some portions of the work of his coadjutors.

In particular, the section on Hygiene is a sample of book-making of the worst kind. Admitting that the space at the compiler's disposal (130 pages) was little enough in all conscience, we yet submit that what was written should bear comparison, bulk for bulk, with that part of Sonnenschein's *Handbook* which treats of similar subjects; whilst those who wish to see what can be said on such topics, in a very few pages, may compare Dr. Proctor's *Hygiene of Air and Water*, or Dr. Stocker's *Hints on Health*. The fact is, this portion of the work is spoilt by a pretentious universality, which aims to include gas and gussets, potatoes and perfumery, latrines and lupanaria, petticoats and police, chignons and clockmaking; and a thousand other things, mere matters of detail, where principles and practical precepts are required.

We consider this, and the section on the Sphygmograph, the worst parts of the book. The name of Marey, it is true, is mentioned, but the reader looks in vain for any description or directions for the use of any working form of pulse-recorder newer than the somewhat cumbersome instruments of Vierordt. On the other hand, the section on Toxicology, though brief, contains many useful memoranda, and is a great improvement on most previous performances on poisons. Similar commendation may be given to the chapters on Auscultation and Percussion, though rather too brief, and containing one or two notable omissions. We quote a short specimen from this part.

"Lastly, let us mention the singular symptom known as 'Cheyne-Stokes' Respiration,' first observed in 1816 by Dr. Cheyne in Dublin, and of late the subject of much discussion. Stokes has only met with it in fatty degeneration of the heart, or a few weeks before the patient's death. He describes it as a series of inspirations, which reach a maximum, and then decrease in both depth and length, till a condition of apparent entire cessation of breathing is reached. This may last so long, that the bystanders may deem the patient dead; a feeble inspiration, followed by one a little stronger, marks the beginning of a fresh ascending, and then descending series of breathings, as before. The decrease in the depth and length of the respirations is just as regular as the preceding progressive increase. Every successive inspiration becomes shallower than the one which preceded it, till they become almost imperceptible, and a condition of apparent apnoea sets in. The deepest inspirations assume the aspect of dyspnoea. It is not easy to explain these phenomena. Schiff, Traube, Frantzel, etc., have endeavored to seek the true pathology from clinical and *post mortem* room studies. According to the two former observers, there are two distinct conditions under which we meet with this kind of breathing; *a*. Cases in which the heart is all right, but the cranial contents are structurally affected; and, *b*. Cases where the cranial contents are uninjured, but the heart has undergone structural changes. In both kinds, similar conditions underlie the respiratory phenomena, viz., a defective supply of arterial blood to the medulla oblongata, the great centre for respiratory action. The old notion, that it is only in cases of fatty degeneration of the heart that we find this kind of breathing, may be considered quite obsolete, since it has been noticed in many other kinds of disease. It must, however, be confessed, that there is yet much to learn regarding the true pathology of the 'Cheyne-Stokes' Respiration."

The introductory chapter on Thermometry is far from being a mere *réchauffé* of Wunderlich. There is a good deal of original matter from H. Roger, Alvarenga, Sydney Kinger, Guntz, and Bäumlér. Under the Ophthalmoscope, there is but slight reference to the medical uses of that instrument as distinguished from its special surgical applications. The chapter on Anomalies of Speech omits all notice of aphasia and the kindred lesions met with in some forms of insanity. The chapters on the Laryngoscope strike us as good, though the diagrams are simply hideous. Urology contains, in eighty pages, one of the very

best accounts of the urine, and its constituents in health and disease, we have ever met; and in this section the woodcuts are very clear. So are most of the optical diagrams. In the chapter on Histology, some familiar things, such as blood, elastic tissue, spermatozoa, and the like, are scarcely to be recognised in the woodcuts by eyes only accustomed to see such things under the defective lenses supplied us (*teste* our author) by English microscope-makers!

Electro-therapeutics is one of the best sections in Dr. Kraus's compendium. It is clear, practical, and has, in common with other portions of the book (but perhaps rather more than these), interesting historical memoranda on the various subjects mentioned. A practitioner possessing this, would not only clearly understand the distinctions between *constant* and *interrupted*, *primary* and *secondary*, *induced* and other *currents*, and such words as *electrodes*, *faradisation*, and the like; but he would be able, also, if at a distance from instrument-makers, to construct apparatus for himself. With one more extract, this time from the section on the Microscope, we take our leave of a book which, in spite of the faults we have indicated (and hope to see amended in future editions, whether German or translations), is a perfect storehouse of facts, and a true "pocket cyclopædia" of medical science. This extract (from pages 223-226, with a few omissions) gives a fair idea of the style of the book.

"Fungi include some of the simplest cell-forms. They are free from starch and chlorophyll, but very rich in nitrogenous substances. The simplest forms of fungi are uni-cellular organisms. The more developed produce a delicate layer, or *thallus* of cells, extended lengthwise. From this thallus, also called *mycelium*, either separate cells, called *spores* or *conidia*, are simply evolved; or from these again a new colony is developed; or a fresh formation of spores takes place, it may be by a special fructifying organ (Sporangium); or the further development takes place by *division of the mycelial threads*. If the mycelium is tough and thick, and requires a period of rest before further development, it is called a *Sclerotium*, or permanent mycelium. The branches or stalks bearing the conidia, and originating in the mycelium, are called *Hyphæ*. Different genera of fungi are constituted by the hyphæ sometimes bearing the conidia on their summits, sometimes at their sides. The conidia themselves are sometimes simple, sometimes divided by partitions (chambered conidia). Very often they are numerous, aggregated, and surrounded with a covering or sheath (peridium). Besides these modes of reproduction, we sometimes find some individual cells of the mycelium separated from it, and thickened at their summit; these also promote the multiplication of the individual; and are called *Macrogonidia* or chlamydospores. Very often two kinds of spores can be recognised, and divided into male and female organs of fructification, *Antheridia* and *Oogonia*.

"Microscopic fungi are so extremely polymorphous, that accurate study of their growth and development has led many to the conclusion that different varieties may originate from one and the same cell, according to the soil in which it is placed. The natural history of these minute bodies is, however, still very obscure. The separate forms of parasitic fungi may be grouped under the following types:

- "(a) granules, and granule-forming protoplasma;
- "(b) yeast, properly so-called (in separate free cells);
- "(c) chain, and string-forming germinating yeast,
- "(d) submerged, and
- "(e) true aerial moulds, and
- "(f) mycelial forms of very varied structure."

After some further definitions and explanatory figures, which are very clear, we are told—

"A natural grouping of these forms is given in the following table:

"I. Yeast Fungi, embracing—

"A. True Yeast—a, *Micrococcus*, granular yeast; b, *Cryptococcus*, germinating yeast; c, *Arthro-coccus*, chain-like yeast.

"B. Yeast, with fibrillated, or chain-like structure—a, *Leptothrix*, granular yeast; b, *Horrmisium*, germinating yeast; c, *Mycoderma*, chain-like yeast.

"C. Yeast-Colonies—*Sarcina*.

"II. Mould like Forms: Mildew—

"A. True Mildew, aerial mould: a, *Mucor*, mould with heads; b, *Penicillium*, pencil moulds.

"B. Pseudo-mildew, mould in the interstices of a tissue, or in fluids: a, *Oidium forms*, *Oidium*, *Achorion*, *Microsporon*, *Trichophyton*; b, *Smut*, or *brand mildews*, *Ustilago*, *Tilletia*."

This is followed by several pages on parasitic diseases in which fungi are found.

Dr. Kraus deserves the thanks of the profession for originating and carrying out his idea, and we can assure him that our criticisms, even when severe, are not unfriendly.

ON THE CONDITION OF THE MOUTH AND TEETH DURING PREGNANCY. By OAKLEY COLES, L.D.S., Dental Surgeon to the Hospital for Diseases of the Throat. Pp. 31. London: Wyman and Sons.

THIS little treatise deals with—1. The changes and general condition of the teeth during pregnancy; 2. The condition of the gums; 3. The oral secretions, with their changes and influences upon the teeth; 4. The neuralgia of pregnancy; and, lastly, the remedial agents useful during pregnancy. The author has evidently paid considerable attention to the subject, and gives many useful hints as to the management and relief of the distressing toothache and neuralgia complicating pregnancy.

An acid state of the saliva seems to play an important part in the production of caries, and this acidity almost invariably accompanies rheumatic pains in the face; whereas, in pure facial neuralgia, the saliva is alkaline—a point well worthy of notice in endeavouring to arrive at a correct diagnosis. The remarks on treatment are practical, and well repay perusal. Much unnecessary suffering might be saved by a more careful study of the subject, and the practitioner will do well to carry out the suggestions offered by the author.

REPORTS AND ANALYSES

AND

DESCRIPTIONS OF NEW INVENTIONS

IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

A NEW INSTRUMENT FOR THE DIRECT APPLICATION OF TOPICAL MEDICINES TO THE VAGINA.

M. DELISLE of Caen has lately laid his new apparatus, which he calls a vaginal *porte-topique*, before the Paris Academy of Medicine. The instrument is manufactured by M. Galante of Paris, in vulcanised India-rubber. It gives to women the facility of applying to the vagina, and even to the neck of the uterus, all those medicinal substances which the physician wishes to have applied locally, such as plugs of wadding or lint, sponges, bags filled with medicinal powders, or poultices, ointments, and powders of every kind, with as much facility as she can give

herself a liquid injection. The *porte-topique* will also permit the patient to apply, according to the physician's orders, all vaginal topical applications, whether solid, soft, or pulverulent; and even liquid topical applications, in which wadding, lint, amadou, or sponge have been soaked, or which have been absorbed into a powder or a poultice. This topical application, made by the patient herself, has the advantage of allowing her to repeat every day, and even several times a day, dressings which

Fig. 4.—Arrangement of the instrument to take hold of the top (c) of a plug of a bag (s), or of a sponge at the puncture of the piston.

usually are only applied once or twice a week. The physician may also substitute in his prescriptions the injection of a powder, of an ointment, or even the application of a plug or bag soaked in liquid injection, and consequently replace the rapid and temporary action of a liquid by the continuous action of a permanent topical action.

SYPHILITIC MENINGITIS.—A case is recorded by Brulberger in Virchow's *Archiv*, vol. IX, in which a man aged 30, the subject of syphilis, suddenly fell senseless after a very moderate use of alcoholic liquors, and for eight days was quite incapable of motion. The cutaneous sensibility was but little, if at all, impaired; and the electric irritability of the muscles of the lower limbs was nearly normal (at least at the beginning). After suffering for two years, he died. The changes found in the central nervous system explained all the symptoms of the illness, as well as its sudden commencement. There was extensive meningitis of the base, by which the membranes appeared to be converted into a thick grey yellowish mass (paralyses of the cranial nerves, however, were not observed). The vertebral and basilar arteries were adherent to this mass; their lumen was dilated, and their walls thick and rigid. The arteries in all other parts of the body were healthy. The whole of the cervical spinal cord was narrowed by the thickened membranes; and there were adhesions of the membranes in several parts of the vertebral canal. The grey matter of the cord was atrophied; the central canal was dilated; the cord itself was studded with hemorrhages, to the occurrence of which Brulberger is disposed to refer the sudden attack. There were also indications of syphilis in other organs.

BRITISH MEDICAL ASSOCIATION:
SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, JANUARY 16TH, 1875.

EXCRETION AND THERAPEUTICS.

THE assimilation of food entails the removal of waste. When food is taken and digested, it serves two distinct ends. Part of it is burnt up, either forthwith or at some more distant date, while another portion is utilised in tissue building and repair. The products of such assimilated material are, speaking broadly, carbonic acid, water, and nitrogenised matters in various stages of oxidation. These excreta, if retained, act in a prejudicial manner. Of water, there is little to be said, though certain mischievous results follow when its excretion is interfered with. Carbonic acid is a well known poison, whether respired or generated within the body, and but insufficiently excreted. Carbonic acid poisoning is the great danger of bronchitis, where the patients do not die so much because they cannot inspire oxygen as because they cannot get rid of their carbonic acid, the experiments of Rosenthal and Pilger notwithstanding. The disastrous consequences of nitrogenised waste matter in excess in the fluids of the body are well known, whether as attacks of gout, as other manifestations of lithiasis, or as uræmia—the result of excess of the earlier products of retrograde metamorphosis of azotised matter. At one time, up to a very recent period indeed, it would have been deemed proper to have written “the earlier products of retrograde tissue-metamorphosis”. This we now know to be inaccurate. Much of the nitrogenised waste is the result of the splitting up of albuminous matter in the liver, the resultant products being glycogen and tyrosine, creatine, creatinine, and the other early forms of azotised waste, which by oxidation become converted into uric acid and urea. The products of waste of tissue are also water, carbonic acid, and the above mentioned nitrogenised matters. In consequence of the poisonous characters of these waste matters, they are eliminated from the body by various excretories, and the amount at one time within the organism is kept under ordinarily by the action of one or more of the excretory systems. What these excretory systems are, will next engage our attention.

Water is excreted by the skin, the kidneys, and the lungs. A certain flow of water through the body is essential to the elimination of waste products, many of which are held in solution. Carbonic acid finds its way out of the body chiefly by the lungs. Nitrogenised matters pass off by the skin as well as by the kidneys; but, under certain circumstances, especially of impaired respiration, carbonic acid passes off by the skin; and uræmic diarrhoea is far from uncommon in the subjects of chronic renal disease. We are too much inclined, indeed, to regard the functions of the different excretory organs as being highly specialised, and to lose sight of their common characters of the unity of function which accompanies their homologies of structure.

The different excretory organs of the body are but involutions of the common tegument, and retain in their most elaborated form their primitive characteristics. In the lowliest forms of life, the tiny organism taken as food can be seen to melt away in the speck of sarcoid by which it is engulfed. The waste products pass away from the general surface, and no one part can be recognised as being more especially functional than another. A little higher up, we find a simple short tube, which may be turned inside out, and its intestinal canal converted into a tegument, and its external surface into a digestive canal,

apparently without disturbance to the animal. As we ascend, the scale of creation and evolution gives us more elaborated forms; we find that different portions of the general surface have undergone modifications; certain parts have become limbs, organs of progression, while others again have been converted into organs of excretion. We find that one deep involution of the general surface has become a gastric pouch, which in time becomes a long digestive track, along which are secondary involutions, giving us the salivary glands, the liver, and the pancreas. Another involution furnishes the urinary apparatus, the first sac forming the bladder, with its secondary involutions the ureters and kidneys. In the desquamation of the uriniferous tubules of the kidney during the cutaneous exfoliation of scarlatina, we find a marked clinical instance of the relations of the skin to the epithelial lining of the kidney.

When we come to consider the community of origin of the various excretory organs, we can the more readily comprehend the unity of function which underlies their apparent specialisation.

This is no mere hypothesis nor pure induction unsupported by facts. We are all familiar with the fact that, when there is a defective elimination or excretion of bile by the liver, or when the bile-duct is obstructed by a ligature, the bile passes into the circulation generally, and is found in large quantities in the urine, as well as being excreted by the skin to such an extent as to tinge the linen. Not only so, but it has been found in the pancreatic juice and the mammary secretion. Urea was found in the sweat by Schottin in cholera collapse, where suppression of urine is common. Further examinations were made by different observers, until it has been found that, in the presence of urea, the phosphates and chlorides of the alkalies, the constituents of sweat, are those of urine. Fourcroy had long ago found urea in the sweat of horses. By a series of elaborate experiments, Leube has shown that there is such a relation existing betwixt the skin and kidneys in function, that, when the skin is active, the kidneys secrete less than their normal amount of urea. All who have had much experience are familiar with the urinous odour of the breath, and the ammoniacal character of the vomited matters and the dejections in cases of uræmia. Zalesky found that ligature of the ureters in serpents was followed by an incrustation of uric acid upon the mucous and serous surfaces of the ophidians. An offensive odour of the breath is commonly found along with inaction of the bowels or skin.

We have, indeed, abundant evidence of the capacity of one excretory of the body to supplement the function of another when impaired or suppressed. This leads us up to two general considerations, both of much practical value. One is the supplementing of the function of an organ, when that organ is disabled by disease, by exciting compensating activity in another organ. The second is the true and proper treatment of excessive activity in any organ, when that activity is rather a compensatory action than a morbid process. These are practical considerations of the greatest weight in rendering our therapeutic measures not only more rational, but also more effective.

We are all familiar with the burning skin of pneumonia, which has been attributed to an increase in the cutaneous respiration when the ordinary respiration has been interfered with by disease. In the lower vertebrata, the cutaneous respiration is a much more important matter than it is in man; nevertheless, a certain amount of carbonic acid is normally given off by the skin in human beings. This power of the skin to aid in respiration when the ordinary respiratory organs are the subject of disease, may help to explain the good effects of diaphoretics in the treatment of such ailments. The dilatation of the cutaneous vessels, the increase of moisture on the skin, so favourable to the transpiration of gases, probably increase the cutaneous respiration; and in this we may find the explanation of the beneficial effects of those remedial agents which empiricism has already taught us to employ. Of course, it will not do to overlook the effects of dilatation of the cutaneous vessels, and the consequent enlargement of the vascular area, which produce the same effect upon the circulation as venesection; in fact, it is only bleeding the patient into his own vessels. Probably, in

VOLUME II FOR 1874

JULY TO DECEMBER.

London:
PUBLISHED FOR THE ASSOCIATION BY FRANCIS FOWKE, 36, GREAT QUEEN STREET.

INDEX TO VOLUME II FOR 1874.

A.
 Abdomen, tumours of, 568, 516
 Abdullah Bey, death of, 417
 Abercorn, Duchess of, visit to Dr. Steevens's Hospital, 89
 Abscess, mammary, in infants, Dr. W. Stephen on, 106, 390; Dr. A. P. Wilks on, 139; communications on, 171, 199, 243, 275; retropharyngeal, Dr. Oxley on, 371; of brain from disease of ear, 771; peripleuritic, 777; of liver, 795
 Academy, Royal, medical exhibitors, 37; of Medicine in Paris, proposed changes in, 689
 Action for illegal practice, Apothecaries' Company v. Anderton, 17; for Ebel, Bowles v. Hart, 38; for malapraxis in Otrazo, 57; surgeon against assistant, Gravelly v. Barnard, 118; for railway damages, 229; Pharmaceutical Society v. Day, 254; for neglect, Broad v. Lyle, 283; for a policy, Jay v. Gresham Insurance Company, 281; for libelling a medical man, Buchanan v. Pain, 310; under Sanitary Act, 420; for negligence, Bretsford v. Rigby, 471, 591; for recovery of fees, 749
 Adams, Surgeon-Major A. L., 522
 — Mr. E. J., the Bethnal Green Workhouse Infirmary, 539
 — Mr. W., strangulated femoral hernia relieved by injections of oil, 509
 Addison's disease, Mr. Ferris on a case of, 553
 Addresses, recent, 289
 Adulteration, Committee of Medical Council on, 37, 109, 111; report of Committee of House of Commons, 37; of milk, 117; Act on, proceedings in Parliament regarding, 169; charges for, 625
 Aerated bread, 26
 Africa, North, plague in, 311
 Agricultural implements, preventive surgery in its relations to injuries from, 384
 Aitken, Dr. W., Outlines of Science and Practice of Medicine, rev., 776
 Albumen, Dr. J. Johnson on rare modification of, 618; Mr. G. S. Johnson on certain compounds of with acids, 673
 Alcester, sanitary report on, 633
 Alcohol, Committee on effects of, 532; Mr. T. P. Lucas on action of, 612, 835; Mr. S. W. Moore on action of, 645; Dr. De Chaumont on chronic acid reaction with, 708; Dr. J. Ross on action of, 742
 Alcoholism, Mr. W. C. Garman on, 101; in the upper classes, 373; Dr. J. Russell on, 607; Dr. H. Sutherland on, 610; remarks on, 622. See Alcohol, Drunkards, and Drunkenness
 Alexandria, Mr. W. H. Flower on, 362
 Allan, Dr. J. W., case of acute rheumatism, 277; belladonna in excessive perspiration, 645
 Allbutt, Dr. T. C., mediastinal sarcoma simulating callous mediastino-pericarditis, 300
 Alopecia treated by local stimulants, Mr. Roese on, 615; areata, 709
 Amblyopia in a painter, 712
 Amenorrhoea from absence of uterus, 172
 Ammonia, changes produced in trachea and lungs by, 82; use of in snake-bites, 256
 Amputation, double tibio-tarsal, 829
 Amyl, nitrite of, inhalation of in angina, 682
 Anemia, idiopathic, Dr. Wilks on, 680
 Anesthesia by injection of hydrate of chloral, 90, 193
 Anesthetics, action on red corpuscles of blood, 307
 Anatomy, Dr. Reilern on recent advances in, 271
 Anæsthesia, Mr. Holmes' lectures on treatment of, 12, 106, 138, 158, 170; with paralysis of left laryngeal recurrent nerve, Dr. E. T. Wilson on, 80; in groin and ham of same side, Dr. T. Diver on, 31; double popliteal, 383; traumatic, of neck, 196; of abdominal aorta, 631, 649; of pulmonary artery, 710; double, of thoracic aorta, 712; abnormal opening into spinal canal, 712; of aorta opening into left auricle, 818; popliteal, 819
 Angina relieved by inhalation of amyl, 682; ptericis, 830
 Aniline dyes, tests of, 696
 Ankylosis, fibrous, 794
 Annandale, Mr. T., symptoms of renal calculus relieved by exploratory incision, 768
 Annington, Mr. B., pathology of communicable disease, 292
 Austie, Dr. F. E., obituary notice of, 380, 392; memorial of, 410, 567; resolutions of Committee of Hospital Out-patient Reform Association, 171; of Council of Poor-law Medical Officers' Association, 501

Antagonism of medicines, report of Committee on, 236, 364, 455, 518, 547, 551, 615, 674, 697, 771, 805; remarks on, 779; between strychnia and chloral, 436; between atropia and Calabar bean, 491; Dr. W. A. Richards on, 536; between chloral and Calabar bean, 485; between hydrochlorate and meconate of morphia and Calabar bean, 486; between sulphate of atropia and meconate of morphia, 518, 547, 581; between tea, coffee, cocaine, theine, caffeine, and guaranine, and morphia, 615, 674, 697, 771; between theine and meconate of morphia, 697; between caffeine and meconate of morphia, 698; between guaranine and meconate of morphia, 699; between tea and coffee and meconate of morphia, 771; between extract of Calabar bean and strychnine, 805; between bromal hydrate and atropine, 805
 Antiseptic treatment, M. Demarey on, 505; action of boracic acid and its salts, Mr. B. A. Rigg on, 773; incision as an aid to surgical diagnosis, 794
 Aorta, abdominal, ulcer of duodenum opening into, 528; aneurism of, 631, 649, 818; aneurism of opening into spinal canal, 712; of thoracic aorta, double, 712; double arch of, 818
 Arlasia, description of by Goethe, 19; Dr. J. W. Ogle on, 163; after enteric fever, 507
 Apomorphia as an expectorant, 279; physiological action of, 378
 Apoplexy, cerebral, in a boy, 277
 Apothecaries in Ireland, proposed Bill for license of, 150
 Apothecaries' Hall in Ireland, officers of, 182; regulations of, 342
 — Society of, prosecution by, 17; prizes in botany, 37; visitation of examinations, 77; proceedings regarding conjoint board, 111; Amendment Act, 148; regulations of, 333; assistants, 606; pass-lists, 806. Medical News in each number
 Appendix, vermiform, disease of, 795
 Appetite, morbid, 443
 Arm-presentation, double, Mr. Karkeek on, 773
 Armistead, Dr. W., districts of medical officers of health, 318
 Armstrong, Mr. J., purpura versus flea-bites, 97
 Army, British, the successor to Surgeon-General Watson, 24; changes in medical department, 69, 715, 755; letters on medical service of, 69, 130, 159, 262, 323, 324, 189, 511, 541; returns from Medical Department to General Medical Council, 79; the medical service of and the students, 156; close of session of medical school, 181; pass-lists, 262; appointments, etc., 159, 295, 391, 392, 450, 549, 603, 634, 659, 722, 755, 797; hospital services, 323; candidates' marks, 823, 792; regulations for admission into medical service, 112; remarks on medical service of, 190; obituary, 450, 594, 722; opening of session of medical school, 450; Asiattee war rewards, 549; operation of Contagious Diseases Act, 364, 572, 629, 661, 693, 720, 724, 759, 830; Dr. De Chaumont's paper on pay and emoluments of surgeons, 655, 723, 756; exchanges for medical officers, 714; hospital corps, 756; civil employment of retired officers, 736; duties of regimental medical officers, 737
 — Indian, pass-list, 262, 295; promotion in, 462; civil surgeonship at Benares, 510
 Arsenical poisoning by articles of dress, Mr. R. R. Cheyne on, 643
 Artery, external iliac, ligation of for double aneurism, Dr. T. Diver on, 31; femoral, rupture of, 187; popliteal, aneurism of, 383, 189; common carotid, ligation of with wire, 196; pulmonary, disease of, 649, 794; pulmonary, aneurism of, 710; duodenal after opening into an, 755
 Artichoke, Dr. Copeman on treatment of rheumatism by, 768
 Artinus, lectures on diseases of, 685
 A-camples, Dr. Lockhart Clarke on severe nervous symptoms from, 366
 Ashantee war, Dr. A. A. Gore on, 301
 Ashby, Mr. A., scarlatina at Newark, 119
 Ashby, Dr. W. H., appeal on behalf of family of, 605, 664
 Aspirator, Coxeter and Sons', 83; use of in tapping the chest, Dr. J. Russell on, 173, 404; Mr. A. Gedrich on, 188, 290, 390, 396; Dr. R. D. Powell on, 299; Mr. G. Brown on, 560, 459, 604; Dr. C. R. Thompson on, 118; Dr. R. S. Smith on, 335; Dr. H. Page on, 536; Dr. Heaton on hydatid of liver treated by, 557; Mr. A. Bell on use of in retroverted uterus, 706
 Aspirator-needle, 820

Assault on a medical man, 783
 Assembly, French National, legislation regarding employment of children as mountebanks, 90
 Assistant, action against an, 118
 Association, British Medical, the meeting in 1875, 20, 109, 658, 687, 778, 780; programme of meeting in 1874, 21, 62, 90, 125, 151, 183; list of officers and Council, 41; list of members, 43; scientific grants, 61, 751, 780; proceedings of Committee of Council, 63, 690; remarks on the annual meeting, 85, 147, 183, 227, 307; proposed articles of Association, 129; proposed bye-laws, 121; President's address, 195; Dr. Russell Reynolds's address in medicine, 240, 234; Mr. Cadge's address in surgery, 207, 248; Dr. Matthews Duncan's address in obstetric medicine, 213, 249; Dr. Eade's address in section of medicine, 215; Sir J. Paget's address in section of surgery, 221; Dr. F. Churchill's address in section of obstetric medicine, 223; Mr. Michael's address in section of public medicine, 225; forty-second annual meeting, 231, 247; address of retiring President, and vote of thanks, 241; report of Council, 232; statement of receipts and payments, 233; meeting in 1875, 234; Committee of Council, 234; report of Committee on qualification in State Medicine, 244, 248; report of Parliamentary Bills Committee, 246, 248; report of Committee on registration of disease, 246, 248; members present at annual meeting, 247; report of Medical Reform Committee, 247, 255; report on action of medical officers, 248; special general meeting for incorporation of the Association, 249; State Medicine Qualification Committee, 248; American delegation, 250; Scientific Grants Committee, 248; votes of thanks, 248; dinner, 248, 251; official shown in annual museum, 255; the Association and the public medical services, 262; collection of instruments in annual museum, 290; excursion, 26; letter on annual meetings, 226; general meeting, 596; new branches of, 596, 651
 — Section of Medicine, president's address, 218; mechanism of cough, 257; chronic Bright's disease, 257; action of mercury, 257; lesions of speech in general paralysis, 258; craton-chloral hydrate in megrim, 258; Leamington Spa, 258; convulsions from brain-disease, 258; localisation of function in brain, 258; disease of heart in pregnant women, 259; clinical instruments, scales, and weights, 259; a disease of carpenters, 259; etiology of girre, 259; hydatids of liver treated by puncture, 260; diptheritic paralysis, 260; diptheria, 261; administration of phosphorus, 261; treatment of rheumatism, 262; tumours of cerebellum, 262; lymphadenoma, 262; disease, 262; pathology of a communicable disease, 262
 — Section of Surgery, president's address, 221; lithomy, 282; resection of shoulder-joint, 382; treatment of chronic synovitis, 382; resuscitation from ether form narcosis, 382; administration of laughing-gas and ether, 382; hereditary syphilis in the adult, 382; incision of knee in children, 383; excision of hip-joint, 383; treatment of wounds, 383; double p. p. l. aneurism, 383; pressure in inflammatory enlargement, 383; mercury in syphilis, 383; injuries from agricultural implements, 384
 — Section of Obstetric Medicine, president's address, 223, 381; tensile strength of fœtus, 384; treatment of dysmenorrhœa, 384; application of galvanic cautery to gynaecology, 385; decapitation in shoulder-presentations, 385; rupture of uterus, 386; complex 386; the rectum in relation to uterine disease, 387; instrumental aid in labour, 387; the forceps and venter, 387; maternal impressions, 388
 — Section of Public Medicine, president's address, 225, 319; disease-survey system of Poor-law relief, 319; circulation of paper and public health improvement, 241, 318; local Lyceum, 314; water-analysis, 316; safety in army and navy, 317; end fever, 317; the general distribution of disease, 317; face and public health, 318; districts of medical officers of health, 318; disposal of infectious places, 319
 — Meeting in Banff and Kincardine Branch, annual meeting, 157; presentation in General Council, 157; Report of Council, 157; president-elect and Council, 157; Dr. MacQuibban's case, 157; medical men as jurors, 157; suggested improvement in ordinary meeting, 157; dinner, 157
 — Bath and Bristol Branch, annual meet-

- ing, 155; new members, 155, 593; report of Council, *ib.*; president-elect, *ib.*; votes of thanks, *ib.*; ordinary meetings, 598.
- Association, Birmingham and Midland Counties Branch, President's address, 101, 128; annual meeting, 127; new members, 127, 535; report of Council, 1, 17; votes of thanks, 128; election of officers, *ib.*; dinner, *ib.*; resignation of Mr. Portleat as secretary, 501, 535; ordinary meetings, 535; committee on legislation for habitual drunkards, 535, 719—Pathological and Clinical Section, report, 632; officers, *ib.*; alteration of laws, *ib.*; the late Mr. Elblace, *ib.*; communications, 632; excision of knee, 632, 633; fracture of scapula, 634.

the treatment of acute affections of the respiratory organs, the method of giving a patient a bath in his bed will ere long obtain among adults, as it already does among children. With them, it is easy to roll them up in a blanket wrung out of hot water, the beneficial effects of which are familiar to all; but for adults a more complicated apparatus is necessary. Such apparatus is now easily procured.

When there is any impairment in the functional activity of the kidneys, the resort to supplementary action in other excretory organs is alike the refuge of nature and of art. Where there is imperfect water-elimination, we at once act upon the skin and bowels, and excite them into increased functional activity, to compensate the defective action of the kidneys. It is not, however, in water-elimination alone that efficient aid can be furnished by exciting other organs into high activity—the same holds good of the solid matters of the renal secretion. We have just seen that the elimination of nitrogenised waste is a much more general matter than is commonly supposed. Consequently, when there is any accumulation of azotised waste in the system, we proceed to set the bowels in action, and also to excite the activity of the skin. Long ere physiological investigation had laid bare to us the *rationale* of the measures employed, empiricism had pronounced in their favour. Full doses of cathartics, the more hydragogue the better, and sharp action upon the skin, by any form of bath, are the measures upon which we rely in the treatment of the ailments which are the results of imperfect renal action. If by our measures we can keep down the amount of nitrogenised waste in the system, until the kidneys are once more efficient, the organism is tided over a period of mortal peril; if our measures be insufficient from any cause, then the individual perishes—poisoned by self-made waste. This application of remedies to the relief of various ailments, the result of imperfect excretion, leads us straight up to the question of the proper treatment of what are rather compensatory actions than morbid processes. A good example is furnished by the consideration of uræmic diarrhœa. This is a spontaneous supplementary action of the bowels far from uncommon in adult and advanced life. Here the action of the bowels is not a morbid process to be arrested at all hazards; it is compensatory action, to be conserved until other emunctories are opened. Certain it is that such action ought to meet with no attempt to check it, until other channels are patent. It is so common to meet with a limited bulk of urine in diarrhœa, that the more or less complete suppression of the urine in these cases is scarcely noted. Nevertheless, if the diarrhœa be arrested—and usually very active measures are required to achieve this result ere the function of the kidneys is re-established—the consequence is, that the symptoms of uræmic poisoning come on, and the activity of the treatment is followed by the destruction of the patient. This is an eminently undesirable result for all concerned. The rational and proper plan is to meet such diarrhœa by measures calculated to rouse the action of the skin, to apply hot poultices over the loins, to give gentle diuretics, as potash and buchu, in small doses, and to avoid the further production of azotised waste, which would result if beef-tea were given in any great quantity. By such measures, the case may be steered to a desirable termination; the diarrhœa gradually ceasing as the action of the kidneys is re-established. In practice, it is most necessary to follow the rational indications. Too frequently, it is to be feared, the salvation of the patient lies in the difficulty of arresting the diarrhœa. Many cases owe their good results, not certainly to the treatment, but to the fact, that these preservative processes are hard to check, and that consequently the sick person survives in spite of the treatment.

In gouty bronchitis—and much winter bronchitis in those advanced in life is of this nature—we find that iodide of potassium and warm clothing are the most efficient methods of treatment. But neither of these agents exercises any direct effect upon the bronchial membrane. Yet they exercise no slight indirect action. In this form of bronchitis, the hyperæmia of the lining of the respiratory tract occasioned by the low temperature of the respired air results in a certain amount of mucous flow, and this soon furnishes an excretory surface for the elim-

ination of uric acid. The low temperature arrests the action of the skin, and, the functional power of the kidney being insufficient, an accumulation of uric acid in the blood results, while the bronchial lining furnishes an outlet. The iodide of potassium renders the uric acid or urates soluble, and they wash away in the water-currents of the system, while the warm clothing keeps up the action of the skin. Consequently, we see that the measures we have been taught to adopt are those which are best fitted to achieve the desired end.

It not rarely happens that a diarrhœa which is intractable to ordinary measures yields readily to doses of citrate of potash, and a free flow of urine precedes any abatement of the diarrhœa. There are peculiarities in excretion with which we are not yet familiar. It is not sufficient in lead-poisoning to render the lead soluble by iodide of potassium; an occasional purgative is also indicated. The reason of this is, that the iodide of lead circulates in the portal system, and is being constantly thrown out and reabsorbed. A sharp purgative washes it through the bowels, and so hastens the process of cure by iodide of potassium.

Another point of much importance in the consideration of excretion is that of the relation of anæmia to imperfectly depurated conditions of the blood. We are all familiar with the presence of anæmia in lead-poisoning, in malarial and syphilitic poisoning, and also with other forms of poisoning, as in lithiasis, or the less known but common form of anæmia due to fecal accumulation and reabsorption of fecal matters. In all these cases, the bulk of blood is diminished by the action of the poison—whether by destroying the blood-corpuscles, or by interfering with their formation, is not known. The removal of the poison is followed by improvement, even before chalybeates are administered. Thus, in syphilitic anæmia, the improvement which follows the administration of mercurials is often marked ere iron be given: at times, indeed, the substitution of mercury for iron is at once followed by an improved condition of blood. We all know how desirable it is to combine purgatives with hæmatics when anæmia is associated with constipation. Not rarely in anæmic conditions of lithiasis, or irregular gout, the lips recover their hue, and the anæmia is much ameliorated before iron has been added. In fact, we have abundance of evidence to show us clearly that the efficient elimination of waste matter is an important factor in blood-formation, and that the treatment of anæmia is not the simple matter of giving liberal supplies of food together with chalybeates.

The series of agents denominated alteratives do not possess any mysterious or occult action. They are found in the different excretions; they increase the activity of excretory processes, and, by inducing more perfect depuration of the body-fluids, they lead to other blood-formation; and in so much they form excellent auxiliaries to restoratives and hæmatics.

MR. STANSFELD AND THE SANITARY ACT.

MR. STANSFELD has suffered many things at the hands of many sanitary doctors, he tells his constituents at Halifax; and he is certainly nothing the better, but rather the worse, for their treatment. One peculiarity of his malady shows itself in self-laudation at the accomplishment of sanitary results, in spite of the obstacles thrown in his way by "professed scientific sanitarians," and special reference is made to the British Medical Association. Another and very curious symptom is his belief that these results are his own, and not those of the sanitarians whose opposition he has so much cause to deplore. He says that the desideratum that there should be one local authority for all public health purposes in every place, so that no place should be without such authority, or have more than one, has been fully realised.

If it were so, it is what sanitarians and the British Medical Association have persistently urged on his attention as necessary, and what we were nearly brought to believe before this speech to be still unaccomplished. In subdistricts, boards of guardians are still called on to discharge many public health duties. Vaccination and the prevention of diseases still cause great conflicts of authority, and in some districts the

highways, with their sewers and drains, are still in the hands of the highway boards; and, spite of the sarcastic writing of the *Times*, which says, "No one can twit us with having a mass of sanitary law, vast indeed, but in too confused and contradictory a state to be capable of ready and effectual application", this is precisely the existing state of things. The Act of 1872 did little more than transfer to the guardians the powers before exercised by the vestries—for the whole of England had been mapped out by the legislation of 1865-6 into districts—and in every district there was a sewer authority, with the same powers, obligations, and functions as are now attached to rural authorities. But the areas of these districts are so varying, so conflicting, and so entirely beyond summation or control, that sanitary progress is rendered impossible. The *Times* says it can no longer be objected that all that is wanting is to bring authorities already constituted generally and imperatively into working order. What does this mean? We confess it baffles us; but it is certain that the 49th Section of the Act of 1866 has quite failed in its "imperative" working, and the Act of 1872 in no way increases its power or applicability, or supplies its shortcomings. Sanitarians urged on Mr. Stansfeld—

1. Areas capable of supporting competent Officers.
2. Consolidation and simplification of the existing Law.
3. Unification of Sanitary Authorities.
4. Intermediate Representative County Boards.
5. Encouragement of Local Responsibility and Action.
6. Health-Officers of high status and character.

It is really amusing to read how Mr. Stansfeld, after constantly opposing these recommendations so urgently pressed upon him, is gradually coming round to an appreciation of their truth and importance; and it is still more amusing to notice how he transposes the notes of his speech to enter into unison with the Liberal ideas of his constituents at Halifax. Is it an hallucination on our part that Mr. Stansfeld told the deputations to which he refers that his intention was to lodge power in the Central Office, and that their constant iteration was the necessity of local inspectors, local boards, intermediate authorities, with only a resort to the central body in the last instance? The *Times* would have us believe that everything is in first-rate order, and yet that there are immense difficulties in the way of improvement. Our answer is the same as we have consistently urged on successive governments. Inquire locally by adequate means into the difficulties experienced in carrying into effect sanitary provisions, and the changes which should be made in boundaries and the extent of areas, before commencing any further tinkering legislation, which adds difficulty to difficulty, and every other session a new Act of Parliament to the statute-book, irreconcilable with its predecessors.

Mr. Stansfeld alleges that workmen's cottages have been improved as the direct consequence of the Act 1872. Where is the evidence of this? or that the Guardians like central interference and supervision? It is ludicrous to see what this so-called supervision did in the case of Mr. Stansfeld's inspectors, who, after two days' coaching, were sent into the country to inaugurate the new Act, and where every man hunted his own hare in such a way as to make the Local Government Board a laughing-stock through the whole empire. What one inspector recommended was in the next district disclaimed and disavowed. By one, small areas were held to be imperative; by another, large joint boards were declared indispensable.

The points for which Mr. Stansfeld takes credit are beyond rather than in the Act; and the agreements to employ skilled officers of health over large districts, persistently urged on Mr. Stansfeld and refused, but for which he now wishes to take credit, are only binding at the will of the various authorities combining to procure effective service. Mr. Stansfeld congratulates the nation on the compulsory appointment of officers of health. He forgets to say that his faulty law is satisfied by the appointment of such an officer at £10 a year, and that frequently the salary of the inspector of nuisances has exceeded, if it have not doubled, the salary of the skilled officer. We have not scrupled to assert that the execution of the sanitary law must be confided to

officers of skill and competency, devoting their whole time to the duties of their office, and above fear or favour; a legal adviser, a surveyor, and an officer of health, supervised in an adequately large district by a representative local authority, have always been, in our view, essential to the proper working of these laws. There are circumstances which demand wider areas and larger authority, and this is easily provided for by county or other authorities, consisting of the chairmen of all the boards, to be governed with the addition of an equal number of magistrates, chosen at Quarter Sessions, and acting for a year: this intermediate authority to be a court of appeal, as well as a power for enforcing necessary works. Mr. Stansfeld's speech is full of the decry of centralisation; his acts were full of its extension and application. It has not been successful; and in saying so, we only speak with the voice of the various sanitary authorities in the country.

BABY-FARMING.

"AT Newton Abbot, on Saturday, Betsy Benmore was committed for trial for the wilful murder of the illegitimate child of Mary Phillips." This brief announcement has been going the round of the papers. Betsy Benmore is a woman who takes in children to nurse for hire—in other words, a baby-farmer. Mary Phillips, the mother of the child, swears that it was perfectly well when entrusted to the prisoner's care. She heard nothing from the prisoner for several weeks before the news reached her that the child was dead. If the mother had been contributing a weekly sum for the child's maintenance, communications would necessarily have been kept up between her and Betsy Benmore. The reasonable presumption therefore is, that the child was farmed out on the "lump-sum" system, being taken off the mother's hands altogether by the baby-farmer, in consideration of a given sum. The horrible feature of the "lump-sum" system is, that the baby-farmer has a vested interest in causing or accelerating the child's death. The shorter the time that it lives, the larger her profits. This system was fully explained in this JOURNAL and in a pamphlet published some years ago by Mr. Ernest Hart, and also by several of the witnesses who gave evidence before the Infant Life Protection Committee. The "lump-sum" ranges as high as £20, and as low as 30s. The baby-farmer probably thinks that the gradual extinction of the feeble spark of life in an infant is as little criminal as the Lancashire rough does the slowly kicking a wife to death; but a husband was hung for the latter crime after the last Liverpool Assizes, and at least one baby-farmer has undergone the extreme penalty of the law. At Manchester a baby-farmer was sentenced by Mr. Baron Martin to twenty years' penal servitude for letting a child entrusted to her care slowly starve to death.

The existing law, if firmly enforced (and we have every reason to believe that our present Home Secretary will not exercise the Royal prerogative of mercy rashly), is adequate for the punishment of criminal baby-farming, when its system of foul play to the most helpless of beings has been fully exposed to the light of day in a court of justice. The complaint we have to make is, that the State does not take adequate security from persons who make a trade of nursing infants, that the infants will be properly cared for. The Infant Life Protection Act of 1872 happily asserted for the first time the principle that it is the duty of the State to protect little infants, whose lives are endangered, against their own mothers and those who place themselves *in loco parentis*. The assertion of this principle was a most important achievement in the interests of humanity and social reform; but the application of the principle was of the most limited character. It was originally intended that the protection should extend to a single infant put out to nurse for hire. The protection was not to cease at the end of the first year, but was to continue till the sixth; and provision was to be made for the periodical medical inspection of the infant and of the nurse's dwelling. Mr. Jacob Bright opposed the Bill, and succeeded in persuading the then Government to insist on confining the Bill to the case of "two or more infants" taken in to nurse for hire by the same baby-farmer; Lord Portman, in the House of Lords, excluding any case

where the two infants were twins. The age was cut down to the first twelvemonth; and the system of medical inspection was discarded altogether, the infant being handed over to the tender mercies of "police supervision". What has been the consequence? That, in the entire metropolitan district subject to the jurisdiction of the Board of Works, only ten baby-farmers have been registered; and in some important towns, such as Manchester, it is doubtful whether a single baby-farmer has ever been registered. Baby-farming establishments, where only one infant is taken in at a time, escape registration altogether; and some of the worst cases of dosing or starving infants to death have occurred in these establishments.

Attention has been recently called to the case of Edward Taylor, an infant of three years, who died while in charge of a Lambeth baby-farmer of the name of Davis. According to the medical evidence, "there was not a particle of food in the stomach and intestines". The baby-farm was "in a frightful state of neglect and dirt". Mrs. Davis "was in the habit of going out and locking the child in her room for hours without food or fire." On the day of the child's death, and for several days before it, this model nurse was in a state of beastly intoxication. As the Infant Life Protection Act was originally framed, Mrs. Davis would have been required to register, and have been subject to medical inspection. As she only took in one infant at a time, and that an infant of the mature age of three, she was clearly exempt from registration under the existing law. A curious illustration of the effect of Lord Portman's amendment was afforded by a case which recently occurred in the neighbourhood of Hull. A baby-farmer was recently committed to take her trial for neglecting two infants entrusted to her care, and thereby causing their deaths. A member of the Committee of the Infant Life Protection Society wrote to the local authorities, pointing out that the woman must have violated the provisions of the Infant Life Protection Act, and therefore be obnoxious to its penalties. The reply was: "The woman has not violated the provisions of the Infant Life Protection Act. 'Twins' are excepted from the operation of that Act; and the two infants whose lives were sacrificed were twins!"

There is one remarkable feature connected with the case of Betsy Benmore which it remains to notice. "The Bench", we are told, "committed the prisoner for trial, expressing regret that none of the medical men who were applied to would attend the child. This remark elicited applause in court." What is everybody's duty is nobody's duty. The medical men of Newton Abbot, or at least those of them who were "applied to", had probably their hands quite full of other work. Happily, inhumanity is a charge to which the members of the medical profession are rarely, if ever, obnoxious. There is no class of persons that devotes so large a portion of their time to the relief of human suffering, without any reward except the answer of a good conscience, as the medical profession. The irony of "the Bench" falls blunted and harmless, and so does the applause of the unthinking crowd. But if the provisions of the Infant Life Protection Bill, as originally introduced, had been passed into law, Betsy Benmore, although she only took in one infant to nurse for hire, would have been obliged to register, and the Medical Officer of Health of Newton Abbot would have been obliged to inspect the infant entrusted to her and her establishment. There would have been a special officer told off for this special duty, and there would have been no need to go rushing about Newton Abbot applying for medical aid. The Metropolitan Board of Works felt so strongly the necessity for arming themselves with more ample powers for the registration and supervision of baby-farms, that they placed themselves in 1853 in communication with Mr. Lowe, the then Home Secretary, and urged upon him the advisability of his recommending the Government to introduce a measure for that purpose. Mr. Lowe declined; but Mr. Cross is now at the Home Office, and there is every encouragement to the Metropolitan Board to renew their application. If the Government will not take the matter up, let Sir James Hogg himself introduce an amending measure in the coming session. The class of politicians represented by Mr. Jacob Bright, which thinks

it can detect a conspiracy of medical men against the liberty of the subject in every measure of social or sanitary reform, is, happily, not powerful in the present Parliament.

MANSLAUGHTER BY INFECTION.

THIS week, at Coventry, after a long coroner's inquiry, a verdict of manslaughter was returned against a midwife named Elizabeth Ingram. The evidence showed that she had attended a large number of confinements, and had conveyed puerperal fever to the patients. On the 18th of December, she was cautioned by the coroner to cease from practice, but did not do so. Since then, two inquests have been held on fatal cases she had attended. At the first inquiry, Ingram was censured, and she was committed to take her trial on a charge of manslaughter. Four other cases of puerperal fever have proved fatal. The case is one which presents features of obvious importance. The principle affects medical men not less than midwives. Is it certain that puerperal fever is contagious? Supposing it to be so, is a person who conveys contagion to a patient open to conviction of manslaughter? Such a case raises questions highly important in science and very momentous in practice.

DR. THOMAS UNDERHILL of West Bromwich has qualified as a magistrate for the county of Stafford.

THE Hospital Sunday collection in Liverpool amounted to £8,000. The Unitarian chapel heads the list with £423.

DR. E. M. GRACE, the well-known cricketer, is a candidate for the coronership of West Gloucestershire, rendered vacant by the resignation of Mr. W. S. Garsford, who has held the office for nearly twenty years.

THE proceeds of the opening concert of the third season of the Royal Albert Hall Amateur Orchestral Society, of which the Duke of Edinburgh is president, will be given to St. Thomas's Hospital. The Prince and Princess of Wales patronised the concert.

THE Mayor of Birmingham has presented a cheque for £5,308 to the chairman of the General Hospital, as the proceeds of the congregational collections made in aid of the charity on the last Hospital Sunday. The General Hospital alone has now received from this source more than £26,000.

DR. JOHN WILLETT, of Shrewsbury, is a candidate for a vacant coronership in the county of Salop. His address is awkwardly worded, but it lays just stress on the necessity of medical instruction in a public officer who is to inquire, commonly without other aid than that of a single medical witness, into the cause of death.

A SUM of £1,000, bequeathed by Miss Harrison of Sheffield, has been appropriated by the Turkish Aid Mission Society towards the endowment of a professorship in the medical department of a Christian College established by the society at Aintab in Central Turkey. It is proposed to raise £5,000 in Great Britain for the full endowment of the professorship.

MR. MURRAY promises for the ensuing season a new book by Darwin, called *Insectivorous and Climbing Plants*. It will consist of two parts, the first of which is devoted to a discussion of the sensitiveness of the leaves of *Drosera*, *Dionaea*, *Pinguicula*, etc., to certain stimulants, and their power of digesting and absorbing animal matter; and the second to the habits and movements of climbing plants.

THE HOSPITAL FOR WOMEN.

WE are informed, by good authority, that although the Committee of the Hospital for Women in Soho Square refused to investigate the condition of the nursing in that institution when six of the medical officers stated that improvement was necessary, and felt themselves

obliged to resign their appointments as they could not conscientiously hold office longer under such a régime, the Committee have since discharged, not only every nurse, but even the dispenser and hall porter. The house-physician and matron both resigned almost at the same time that the medical officers ceased to act.

THE DANGER OF ANÆSTHESIA.

UNDER the above title, the *Pharmaceutical Journal* records the death of a patient in the dental chair, whilst under the influence of chloroform, as having taken place at Boston. The medical evidence at the inquest was to the effect that the lungs of the deceased were affected with phthisis, and unable to throw off the influence of the chloroform. The jury, however, returned a verdict that the death was due directly to the inhalation of the chloroform, and added a rider, recommending legislation to prohibit the administration of chloroform, as in their opinion, in the present imperfect state of knowledge respecting its action, its use as an anæsthetic is quite unjustifiable. The *Scientific American* deprecates special legislation against the use of chloroform as an anæsthetic, which it considers to be unnecessary, because the growing tendency of the medical profession in the United States is to use either pure sulphuric ether or a mixture of chloroform, ether, and alcohol, whilst the employment of nitrous oxide in dentistry is greatly extending.

CLINICAL SOCIETY OF LONDON.

AT the annual meeting of this Society, held on Friday last, the gentlemen whose names were published in the *BRITISH MEDICAL JOURNAL* of the 2nd instant, and who had been nominated by the Council, were unanimously elected as officers of the Society for the ensuing year. The reports of the Council and of the Treasurer were read, and both contained encouraging accounts of the condition and prospects of the Society. The Council's report dwelt at some length upon the debate on pyæmia, which occupied four meetings last spring, and which, although it was a novelty, was a great success. Its publication *in extenso* had added considerably to the expense of the *Transactions*, but had greatly enhanced the value of the volume. Members of the Society were urged to bring forward for discussion cases which had been thoroughly reported in all points. The Treasurer's report stated, that the present yearly income of the Society was about £288; the annual expenditure about £250; the balance in hand about £100; and the amount invested in consols £300.—Mr. Hulke, in proposing a vote of thanks to the President and Vice-Presidents, remarked that, during Mr. Hewett's tenure of office, he had been only once absent from the presidential chair.—Mr. Mac Cormac seconded the proposition, which was carried by acclamation.—Mr. Prescott Hewett thanked the meeting for the vote of thanks they had just passed, and thanked all the members for the support they had given him. He begged leave to congratulate the Society on the new President they had just chosen (Sir William Jenner).

THE OBLIVATION OF STAMMERING.

IN a lecture on singing, speaking, and stammering, delivered at the Sunday Lecture Society on the 3rd instant, by Dr. W. H. Stone, the lecturer mentioned a fact not generally known, that the late Bishop of Winchester suffered from stammering in his youth. By careful treatment, however, this defect was obliterated, and Dr. Wilberforce, as is well known, subsequently became one of the most easy and agreeable of speakers.

COLD AND ALCOHOL.

ON New Year's Day, a private of Her Majesty's Fusilier Guards had leave of absence, and visited various public-houses in the metropolis in the course of the day. He became very jovial; and at midnight, when going home with a companion, he suddenly staggered into his friend's arms and died forthwith. At the inquest, it was proved that the cause of death was congestion of the lungs, brought on, the jury said, by the intense cold. Doubtless the cold had a great deal to do with it; but the repeated changes of temperature to which the lungs

were exposed in the visits to the various public-houses, had also something to do with it. Probably these visits took their origin in the popular impression that alcohol in all its forms increases the body-heat, and that the different drinks taken would keep out the cold. The consequence, however, was not in accordance with this view, and in the cold of midnight the vasomotor disturbance of the pulmonary circulation became so great that fatal congestion of the lungs came on. In all probability there was a general lowering of temperature from the action of the alcohol upon the cutaneous vessels, and the general chill aided in the production of the pulmonary congestion. The lesson taught is one with which we are familiar enough; but unfortunately it will probably affect but little the erroneous impressions which obtain about the action of alcohol, as to which it cannot be too widely known that it lowers instead of raising the temperature of the body.

BLIND BEGGARS.

WE observe that, at a meeting of the Ipswich Blind Institution, Lord Hatherley commented on the evil resulting from giving to public mendicants. With this view we entirely concur. Those who have the longest experience among the blind, are satisfied that, as a rule, those who beg in the streets are unworthy of relief, and it is better not to give at all than to give indiscriminately; at the same time, there is another side to this question. There are not a few among blind beggars who feel the degradation acutely, but who prefer this life to their only alternative of going into the workhouse. If such persons be not rescued from the streets, they are likely to lose the sense of shame, and to become beggars for life. The principal agencies at work against mendicancy among the blind, are the associations for their employment, which now exist in most of our large towns; and societies, of which the Indigent Blind Visiting Society is the principal, which, besides raising the moral and intellectual status of the blind, gives relief to those who are unable to maintain themselves, but in an organised methodical way. The better the general and technical education of the blind becomes, the smaller the residuum to be dealt with by way of charity; but what is important to remember is, that from old age, infirmity, or other causes, that residuum must always remain a large one, and that the way to deal with it, is not to ignore its existence, or to hand over all such unfortunates to the workhouse, but to assist each case by kindness and wisdom, and by such machinery as will render acting from impulse or deception alike impossible.

PHYSICAL TRAINING FOR SOLDIERS.

PHYSICAL health and physical strength, we are told, are the objects now to which the military authorities must chiefly attend if they wish to improve our forces. Powers of endurance, activity of body, and rapidity of locomotion, are points to be looked to in the training of our soldiers. We have remarked, in our columns, on the necessity for more regard to the subject of proper physical training than it has received; a necessity which is forced upon those whose life, in a great metropolis, especially tends to the deterioration of health. What do we imply by training but the means by which the development of force and the power of regulating the movements of the body are secured. For a soldier, what we most require is activity of motion. We cordially agree with the remarks which a contemporary makes on the subject of military training. We should like to see less drilling and more gymnastic exercise. What assistance can the stiffness of the military drill afford in the hurried assault or the quick retreat? Let us learn a lesson from classic wisdom, and develop the physical powers of our soldiers to the full extent, which the various demands of active service require. It is a question which ought to interest the members of the medical department of the army; and it is to them that we must look for the careful instructions which ought to regulate the system of gymnastic exercises. There is Professor Parkes, and there are many others, who are fully competent for this important service, and to whom the country will feel grateful for the exhibition of energy and scientific knowledge in the work of the physical training of our national defenders.

SHELTER FOR CABMEN.

We heartily applaud the movement which has been set on foot, having for its object the providing of places of rest and shelter at cab-stands. When the needless exposure which cabmen suffer from the want of such shelter is considered, it can scarcely be wondered at if they should resort to the publichouse to while away the dreary hours in which they are waiting for a fare. It is not creditable to a city like London that it is only now beginning to recognise this fact. In Liverpool and other large provincial towns places of shelter have been provided for the men, and do much to promote the health and comfort of an useful and large class of public servants.

A RING IN THE WIND-PIPE.

THE successful removal of a ring from the larynx by laryngotomy was performed (for the first time in America) in New York recently by Dr. G. M. Leferts. The ring had been impacted in the larynx for four years, being swallowed when the child was but six and a half years old. Severe convulsive spasms occurred at intervals, and were increasing in severity and number, when a laryngoscopic examination was made and an operation decided upon. The ring was found grasped by the left aryepiglottic fold, but came away readily when seized by forceps. A tracheotomy-tube was left in for several days, during which there was slight inflammation of the larynx, but the progress made was rapid and satisfactory. The ring was a solid one, about the size of a sixpence, and belonged originally to a watch or locket. The child is now quite well.

KLEPTOMANIA.

At the Manchester City Sessions, on the 9th instant, a lady was indicted for stealing various articles, as sweets and scent, at shops in that town. Insanity was set up as a defence, and successfully, the jury finding that she committed the acts while in a state of unsound mind. The insanity, however, was not inferred solely from the acts. Evidence was forthcoming that she had had an attack of puerperal mania in 1872, and that since this date she had never been quite herself, but had laboured under delusions concerning her children, etc. In this case, the stealing was simply an insane act committed by an insane person, whose insanity was manifested in various ways; and this, we believe, will generally be found to be the case. Such stealing is frequently found in the early stages of general paralysis, and not long ago a paralytic patient actually served a term of imprisonment in one of our metropolitan prisons. But the diagnosis here, as in the case above mentioned, is by no means difficult.

THE BURIAL OF THE DEAD.

MR. SEYMOUR HADEN, in a letter which fills more than two columns of the *Times*, argues that all the evils which the advocates of cremation assert are inherent in the principle of interment, arise from the fact that the dead are improperly buried. Mr. Haden contends that "the natural destination of all organised bodies that have lived and that die on the earth's surface is the earth"; that the source of the evils arising from our present mode of interment is to be found "not in the burial of the dead, but in the unreasoning sentiment which prompts us to keep them unburied for as long as possible, and then to bury them in such a way that the earth can have no access to them". The burial of the body, Mr. Haden asserts, "supposes its resolution by the direct agency of the earth to which we commit it, and that the earth is fully competent to effect that resolution", and he holds that "to seek to prevent this beneficent agency by enclosing the dead in hermetically sealed coffins, brick graves, and vaults, is in the highest degree unphilosophical, since it does but engage us in a vain resistance to an inevitable dispensation, and since it has led us to accumulate in our midst a vast store of human remains in every stage and condition of decay". Mr. Haden proposes that interment should take place in not more than thirty-six hours after death; and that a public officer should be appointed in each district to take cognisance of everything relating to the dead of that district; and he suggests that coffins, if they are used at all, should be of some light permeable material such as wickerwork,

open at the top, "and filled in with any fragrant herbaceous matters that happen to be in season". The earth would not then be prevented from doing its own work of resolution, which would be accomplished in five or six years, and we might bury again in the same ground. Mr. Haden recommends the abolition of the permanent tenure of the ground by the dead, and of the use of brick graves and vaults, and suggests that our dead might be buried in the lowland tracts of alluvial soil on the Kent and Essex banks of the Thames, by which means much of the valuable land in and about the city, now occupied as cemeteries, might be restored to better uses, and the lowlands of Essex and Kent be drained, planted, and beautified, with equal benefit to the land and to ourselves. Cremation Mr. Haden objects to, as a troublesome and wasteful form of disposal of the dead; on this head, however, we differ with him.

MANCHESTER PROVIDENT DISPENSARY ASSOCIATION.

We are glad to learn from the *Charity Organisation Reporter*, of the 6th instant, that the Manchester Provident Association is progressing favourably, and that its Honorary Secretary looks forward confidently to the future. He writes: "We are getting our provident dispensaries gradually to work. We open another on the 5th January, and a third about ten days after. We have fixed upon seven to begin with. It will take time to educate the people; but, as to our ultimate success, I have not the slightest doubt."

THE OBSTETRICAL SOCIETY OF LONDON.

THE annual meeting of this Society was held on Wednesday, the 6th instant, when a large number of Fellows were present. The Treasurer's report, read by the Secretary, showed that the finances were in a very satisfactory state. Considerable additions had been made to the library during the past year: the report of the Honorary Librarian (Dr. Aveling) showing that, "a larger sum than usual had been spent on books; that more works had been presented: that more visitors had entered the library, and that more books had been taken out of it, than in any previous year". The balloting list of officers for the ensuing year, recommended by the Council, was unanimously approved of, Dr. Priestley being the new President. The retiring President, Dr. Tilt, in his address, referred briefly to the loss sustained in their ranks by the death of fourteen Fellows of the Society during the past year, including Dr. Thomas Ballard, Dr. Frederic Bird, and Dr. John J. Phillips. The name of Dr. Bird called to mind the rapid strides that the subject of ovariectomy had made during the last thirty years. In 1843, Dr. Bird performed his first operation, and for the next ten years he remained the chief London operator. In 1850, Dr. Robert Lee, when preparing a paper for the Royal Medical and Chirurgical Society, endeavoured unsuccessfully to obtain from Dr. Bird the records of his thirteen cases, which caused much discussion at the time, and provoked much ill feeling. Dr. Bird subsequently published an outline of all his cases, including eighteen in which an exploratory incision had been made. His conduct with regard to ovariectomy was perfectly honourable; he no more concealed his fatal than his successful cases. The death of Dr. Phillips was felt to be a great loss. He was the very model of a secretary, with great aptitude for business; he was never in a hurry; he had always his work well in hand. He was as judicious in counsel as in debate, and a charming reader. To make up for the losses sustained by death, etc., forty-eight new Fellows had been elected during the past year, making a total, including twenty-seven Honorary Fellows, of 657. Some of the most animated discussions had been the *impromptu* ones on specimens exhibited, which were always of interest. The forthcoming volume of the *Transactions* will be enriched by an index to the fifteen volumes already published, which will prove of great service for reference, the Society being indebted to Dr. Potter for this addition. During the past year, the question of the admission of women as Fellows was discussed by the Society, and negatively almost unanimously, the verdict really meaning that women were not qualified by nature to make good midwifery practitioners; that they were unfit to bear the physical fatigues and the mental

anxieties of obstetrical practice; and that it was unfair to society to encourage women to suppose that they could ever fit themselves to assume the responsibility in some of those formidable obstetric emergencies which too often completely paralyse men of experience as midwifery practitioners. The education and registration of midwives had also been persevered with, but owing to the change in the ministry, legislation on the subject was still in abeyance.

THE PAYMENT OF CLUB DOCTORS.

DR. MILSTED HARMER's proposal for improving the payment of club doctors, which we noticed a few weeks ago, has been unfavourably criticised by the *South-Eastern Advertiser*. Though this newspaper speaks in high terms of the self-denying manner in which medical men, as a rule, discharge the duties of their laborious and responsible profession, and though it maintains that they ought to be well paid, yet it expresses surprise that any complaint is made of the remuneration given by benefit clubs. It maintains that the profession at large does not feel the grievance; and this statement it attempts to prove by pointing to the competition which there is for club appointments. That such competition exists, no one will deny. We have repeatedly referred to it with regret. It is, however, as a mere matter of self-defence that medical men go in for these appointments, knowing well that, unless they accept the terms offered, practitioners from a distance will be introduced to the detriment of the local doctors. It must not, therefore, be taken as a proof that they are satisfied with the remuneration. We can assure the *South-Eastern Advertiser* that such is very far from being the case. There is, on the contrary, a wide-spread and very general feeling of discontent; such a feeling is, in our opinion, well grounded. The class of persons usually enrolled in clubs can quite afford to pay more, and we trust that the agitation upon the subject will not cease until some more equitable arrangement has been arrived at, not merely in Sussex, but throughout the whole country.

SMALL-POX IN MONTREAL.

It would seem that preventive measures, or isolation with regard to small-pox, are needed in this flourishing city. The small-pox is said to be very prevalent indeed there, and is rapidly spreading in all parts of the city. For the past two months the deaths from small-pox have averaged 35 a week, and that in a population of about 120,000. In London, with nearly four millions of inhabitants, 35 deaths a week from small-pox would cause a panic, so that the state of alarm produced by it, in so comparatively small a city, can be readily imagined.

SALE OF POISONS ACT: A NICE POINT.

AN inquest was held on the 4th instant on the body of Celine Marin, a young Frenchwoman who was accidentally poisoned. According to the evidence, she had been suffering from diarrhoea, and sent out for some bismuth, which had been recommended medicinally. The young man who was sent rang the bell of a druggist in Rathbone Place (it being Sunday), and was served by "a lady" with a spoonful of white powder without directions, which the deceased took in the accustomed manner, and was immediately seized with burning pains, in consequence of which Dr. Koupell was sent for; and he did his best to ascertain what poison had been inadvertently served, with a view to administering an antidote. The "lady" who served the poison also called on the deceased with a doctor; and she said it was an unfortunate affair, that it was an accident; but she could do nothing more, as her husband had made many mistakes on similar occasions, and nothing was done to him. The deceased had not been taking any medicine previously. The medical evidence proved that death was caused by the action of corrosive sublimate, which, although it somewhat resembles bismuth in appearance, could be readily distinguished from it by a practised eye, though a woman might readily mistake the one for the other. Winifred Kaut, who sold the poison, was examined at her own request, and stated that she was placed in charge of the house, and had nothing to do with the business carried on by Mr. Kerpinns, who was never there on Sunday. On the 13th of Decem-

ber, a man came to the shop and asked for sixpennyworth of rhubarb-powder and twopennyworth of bismuth. She gave him the rhubarb, and what she verily believed to be bismuth from the same place that she used to take it from. The shop was shut; but she went to the same place, and took it from the same bottle. She should not have given it him on any account whatever if she had not known the man. She saw "bi" on the bottle; but she did not stop as she should have done, and in her hurry she measured him some out in a spoon quickly. It was a very small spoon, and she gave it him nearly full. The coroner, in summing up, said there was no doubt this woman died of having taken corrosive sublimate. By law, persons were not allowed to sell poisons unless they were properly qualified under the Pharmacy Act; but the woman Kaut did not come under the Pharmacy Act, because she did not keep a shop in which poisons were sold. The jury said they wished to have more evidence as to whether the witness Kant had not been in the habit of serving in the shop. The inquest was adjourned for that purpose.

THE HAMPSTEAD HOSPITAL.

AT the last meeting of the Metropolitan Asylums Board, a resolution was carried in reference to the Hampstead Hospital, directing the local committee "to proceed, under the reference to them of the 24th October last, to obtain plans for the construction of the buildings at Hampstead". An amendment was moved by Mr. Marshall, the representative of Hampstead on the Board; and all the arguments against placing the hospital near the heath were repeated, but in vain. The motion was carried by twenty-eight votes against four.

THE REGISTRAR-GENERAL'S WEEKLY RETURN.

It is announced that, from the beginning of this present year, the weekly return will contain information relative to the births and deaths registered in London and twenty other large cities and towns in the United Kingdom, having an aggregate population of 7,739,490 persons; and, in addition, will also be found similar facts relating to an "outer ring" of parishes situated around the Registration Division of London, of which the estimated population is 762,007. The population embraced by the enlarged weekly return will, therefore, be eight millions and a-half. The return will also contain information respecting the current death-rate in twenty-four great cities situated in all parts of the world, and containing a population of about ten millions. In the United Kingdom last week, 6379 births and 5834 deaths were registered in London and twenty other large towns. The mortality was at the rate of 39 deaths annually in every 1000 persons living. It was 45 per 1000 in Edinburgh, 66 in Glasgow, and 42 in Dublin. In seventeen English provincial large towns, the rate averaged 39 per 1000 against 35 in London. It was least of all, 19, in Portsmouth; and as high as 44 in Liverpool, 45 in Bristol, 48 in Salford, and 49 in Manchester. In London, 2853 births and 2296 deaths were registered; the births exceeded the average by 346, and the deaths by 615. The annual death-rate was 35, a result which may be attributed to the low temperature which prevailed until, and including, the 1st instant. To the principal zymotic diseases 184 deaths, being 84 below the average, were referred. Scarlet fever caused 61 deaths. Cold weather prevailed without interruption from December 9th to January 1st, both days inclusive; during this period of twenty-four days, the mean temperature averaged 31.1 deg., which was 7.9 deg. below the average. The deaths referred to diseases of the respiratory organs, which, in the five preceding weeks, had averaged 703, rose last week to 804, which exceeded the corrected weekly average by 380; of which 523 resulted from bronchitis alone. The mean temperature of the air last week at Greenwich, was 43.1 deg., or 6.6 deg. above the average. Rain fell to the extent of .12 of an inch.

CLUB-PAYMENTS.

A CIRCULAR has been issued by the North Wilts Medico-Ethical Association, notifying to all members of sick benefit societies that the medical men in North Wilts have resolved unanimously not to undertake or

continue to attend any club at a less rate than four shillings per member *per annum*; oddfellows and foresters, five shillings; shepherds, six shillings; druids, seven shillings; and a fee of two shillings and sixpence for examining a candidate desirous of entering. "No clubman possessing or occupying premises rated at £10 shall be entitled to medical attendance". "All clubmen to apply for attendance or advice from 9 A.M. to 10 A.M. except in cases of emergency". This new code has been issued upon very brief notice, and as it decides that it is to take effect from the "coming year" the clubs are all taken by surprise, and are by no means satisfied with this peremptory order.

ROYAL COLLEGE OF SURGEONS.

THE following is the programme of the ensuing lectures at the Royal College of Surgeons. On Monday, February 1st, Professor Erasmus Wilson, F.R.S., will commence his course of six lectures on Dermatology, and will be succeeded by Professor W. K. Parker, F.R.S., who will deliver eighteen lectures on the Structure and Development of the Skull, in continuation of his course of last year. Professor Henry Lee, F.R.C.S., will deliver six lectures on Syphilis and on some Local Diseases affecting the Organs of Generation; and Professor William Turner, F.R.S.Ed., will deliver three lectures on the Comparative Anatomy of the Placenta. Mr. Le Gros Clark, the President of the College, will deliver the Hunterian Oration on Saturday, February 13th.

UNIVERSITY OF LONDON.

A MEETING of Convocation will be held on Tuesday next, January 19th, when the following will be the order of business. The Chairman will take the chair at 5 P.M. A. P. Hensman, B.A., and G. Serrell, M.A., will move the following resolution: "That, in the opinion of Convocation, it is desirable that women should be permitted to take degrees in Arts in this University." Sir William Jenner, Bart., M.D., and F. T. Bond, M.D., will move the following resolution: "That, in the opinion of Convocation, it is desirable that a special examination be instituted in this University in the subjects which relate to Public Health."

DEATH AFTER INTRAVENOUS INJECTION OF CHLORAL.

THE intravenous injection of chloral to produce anaesthesia for surgical operations (and in the treatment of acute tetanus), introduced by M. Oré of Bordeaux, and practised in ten or twelve cases by MM. Deneflé and Van Wetter, has, in a case of ovariectomy, been followed by death, before completion of the operation, which was performed by Dr. Lande of Bordeaux. The patient had lost a good deal of blood; to this the death is attributed by the reporters of the case; but it will probably be thought that the case illustrates some of the inherent dangers of this mode of producing anaesthesia.

SCOTLAND.

THE Paisley correspondent of the *Glasgow Herald* says, that, during the past week, the death-rate in Paisley was sixty-five per 1,000 *per annum*.

SCIENCE LECTURES IN GLASGOW.

FOLLOWING the example of some of the other large cities, Glasgow has started an association for the purpose of having lectures on scientific subjects, by eminent men in various departments. This winter, lectures are to be delivered by Professors Roscoe, Sir Wm. Thomson, and Williamson, and Dr. Carpenter.

THE EDINBURGH MEDICAL MISSIONARY SOCIETY.

WE have received the Report of the Edinburgh Medical Mission for 1874. This Society has now been in existence for thirty-three years, and, from a small beginning, its operations have gradually expanded. It has educated and trained many young men who are now labouring as fully qualified medical missionaries, both at home and abroad, and

its success has led to the establishment of similar institutions elsewhere. At the dispensary in the Cowgate of Edinburgh, "the number of patients registered, only on their first visit, during the past year, is 4051; 1575 patients were visited at their own homes, 307 poor women attended during their confinements, and 172 children vaccinated". In addition to the work conducted at the dispensary, there is a training college in connection with the Society, where there are now thirteen young men carrying on their education at the University with a view to becoming medical missionaries. Nurses for the sick poor are also trained and employed as agents of the mission. As the premises in the Cowgate have for some time been found quite insufficient, it is proposed to erect a suitable building, in which all the branches of the work may be carried on, as a memorial to the late Dr. Livingstone. The estimated outlay for this undertaking is £10,000, of which sum nearly £4000 has been already contributed.

IRELAND.

THE total amount collected on Hospital Sunday in Dublin and the surrounding district was £3,300.

THE births registered in Dublin for the week ending January 2nd amounted to 205, and the deaths to 269. This increase in the death-rate over the birth-rate was principally due to the cold and damp weather, which raised the deaths from diseases of the respiratory organs from 47 in the previous week to 88 in the past week.

TYPHOID FEVER IN THE GUARDS.

WE hear that the typhoid cases at the Beggar's Bush barracks have been only three in number; two of the patients, Captain Van der Weyer, and, Captain Langham, have, unhappily, died; the third patient, not an officer, recovered. The origin of the disease has not been traced to any local cause; and, in the case of Captain Van der Weyer, it is believed that it was not contracted in the barracks.

THE LATE DR. JOHN O'DONNELL.

THIS veteran member of the profession has just died at the advanced age of nearly ninety years. He was present at Waterloo, and retired on half-pay in 1825; and, since then, had resided at Ballyshannon, acting as surgeon to the constabulary, coastguard, and recruiting services. He was much respected, and his funeral was attended by a large number of the local gentry and townspeople of Ballyshannon.

THE PUBLIC HEALTH ACT.

AT a special meeting of the Corporation of Limerick held last week, the salaries of the sanitary medical officers were increased from £10 to £20 *per annum*. They had previously been fixed at £10; but pressure from the Local Government Board obliged the Corporation, much against their inclination, to change them to their present amount.

SCARLATINA IN DUBLIN.

THE deaths from this disease during the last eighteen months amount to 1,012; and, in reference to this epidemic, the Dublin Sanitary Association lately communicated with the Public Health Committee of the Corporation, requesting them to issue placards for the purpose of warning the inhabitants of infected districts of the necessity for disinfection and the isolation of patients, etc. The Public Health Committee, however, have refused this very reasonable request, and state that they consider that the proper discharge of their duty by the medical officers, and by their sanitary staff, is sufficient for any emergency. This matter has been repeatedly urged upon the Public Health Committee, but that body object, afraid of causing a panic by the issuing of these placards! It has, however, been suggested that the Dublin Sanitary Association, by a trifling subscription from its members, could easily distribute or post up these warnings and instructions, which they justly consider necessary.

WHAT HAVE EXPERIMENTS ON ANIMALS DONE FOR PHYSIOLOGY?

II.

AN eminent physiologist, to whom we have put this question, has favoured us with the following reply.

You ask me to state my opinion as to the question, whether or not the science of physiology has been materially advanced by the practice of making experiments on living animals.

The only way in which a correct opinion can be formed on this subject consists in estimating the proportion in which the fundamental facts of the science have been derived from such experiments. To do this completely, would be a long and difficult task, though not impossible; for in every course of physiology, in every text-book, there is found ready to hand such a synoptical view of this subject as is calculated for his purpose. Any intelligent student who has carefully read through some one of those elementary treatises on physiology which represent the present position of the science, such as those of Ludwig, Brucke, Wundt, Fick, or Hermann, would, I think, be competent to form a reliable opinion on the subject.

In examining any such work, he would find that each chapter might be described as consisting of little more than a system of experimental results, stated and arranged in such order as to exhibit to the reader their mutual bearing on each other. He would find, in short, that of all sciences physiology is, at the present stage of its progress, more entirely experimental than any other, so that the physiological teacher or writer is compelled by the nature of his subject strenuously to guard against laying down general principles or giving any shape to his conclusions more definite than that which they necessarily derive from their experimental basis.

I have this morning set down a series of elementary questions on the great functions of respiration, circulation, digestion, and secretion. I send them to you. You will, I am sure, agree with me that they are all very elementary—such, indeed, as might with propriety be set to a student at the end of his first course of physiology. Yet, not one of them could be answered without stating the results of experiments on animals. The obvious significance of this fact is that, if experiments ought not to be made, physiology ought not to be taught, and students ought not to be examined in it. If it be wrong to obtain experimental results, it is, at least, equally objectionable to use them.

I may add, that I do not think it at all likely that experiment will be less needed in physiology for some time to come than it is at present. Anyone who is willing to take the trouble to cast his eye over the records of a recent physiological research as embodied in such works as Ludwig's *Arbeiten*, or Flügel's or Du Bois-Reymond's *Archiv*, will have no difficulty in satisfying himself that the rapid progress which is now being made in the application of the exact methods of chemistry and physics to the investigation of the phenomena of life, would almost entirely cease, were the lower animals exempted from lending their unwilling aid to the physiologist in his laborious investigations. It is further to be considered in reference to this point, that we have only, as it were, just attained to that exactitude and method in experimental work which gives to such work its highest value, so that there never was a time in the history of physiology or pathology at which the competent investigator could look forward so confidently to the attainment of valuable results as he can at the present moment.

I do not imagine that among the many intelligent and highly educated persons who are now agitating against what they call vivisection, there are any who seriously intend to obstruct the progress of scientific investigation. But I have no doubt that many either forget, or were never aware, that it is by the method they so stigmatise that every great step has been made in the acquirement of the knowledge, which we now possess of the physical and chemical processes which constitute our bodily life.

LIST OF QUESTIONS.

Circulation.—1. State by what mechanical agency the circulation is maintained, and (approximately) what quantity of mechanical work is done per minute in maintaining it.—2. What is the velocity of the blood-stream in the great arteries: by what means can it be measured?—3. Describe the vaso-motor nervous system, and state what is known as to the situation of the vaso-motor centre.—4. State what is known as to the functions of the nerves of the heart. By what channels is the influence of the cerebro-spinal nervous centres exercised on the heart?—5. Describe the capillary circulation, referring to the modifications it undergoes in irritated or injured parts.

Respiration.—6. Explain the fact that the organs contained in the thoracic cavity are exposed to a pressure less than that of the atmo-

sphere. Prove the fact itself, and state its influence on the circulation.—7. State what is the action of the internal intercostal muscles in respiration.—8. Describe the phenomena of dyspnoea, and prove that they are dependent on defects of oxygen, not on excess of carbonic acid.—9. Prove that the carbonic acid discharged in respiration is partly derived from the decomposition in the pulmonary capillaries of the carbonates of the blood.—10. What are the functions of the superior laryngeal nerve in respiration?—11. Describe the absorbent system of the lungs.

Animal Heat.—12. What grounds exist for believing that the cerebro-spinal nervous system exercises a direct influence on the temperature of the body?—13. Describe the distribution of temperature in different parts of the body of the higher animals, and state what is the probable temperature of the blood in man.

Digestion.—14. Explain the fact that during mastication of food the secretion of saliva is increased. State by what changes in the salivary glands this is accompanied.—15. Explain and account for *post mortem* digestion of the stomach.—16. Explain the mechanism of vomiting.—17. State what are the effects of reabsorption of the colouring matter of bile, and explain its mechanism.—18. Prove that the liver contains in large quantities a substance which is convertible into grape-sugar, under the influence of amylolytic ferments.—19. Describe the peristaltic contraction of the intestines, and state by what nerves and nervous centres it is governed.

Kidneys.—20. State what is known as to the conditions on which albuminuria depends.—21. State what is known as to the seat of origin of urea in the animal economy.—22. Describe the absorbent system of the kidney.—23. Describe the structure and functions of the ureters.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

At the Quarterly Meeting of the Council of the College, held on Jan. 14th, a resolution was brought forward by Sir James Paget, and adopted by the Council, the purport of which was to propose a method of appointing Examiners under any conjoint scheme for an examination for practice in England, which method, if approved, may be submitted to other authorities co-operating in such scheme, and, if accepted by them, may be adopted by this College in the event of its obtaining the Enabling Act. The outline of the plan is as follows: The appointments of Examiners to be divided among the co-operating authorities; each authority to make the appointments assigned to it in such way as it may think fit; the appointment of not fewer than ten Examiners, nor less than one fourth of the whole number, including therein not less than three-fourths of the Examiners in Surgery, and not less than half of those in Anatomy and Physiology, to be assigned to the Royal College of Surgeons; the Universities to appoint one fourth of the Examiners in each of the subjects of examination; and the rest of the Examiners, including one-fourth of those in Anatomy and Physiology, and three-fourths of those in all other subjects except Surgery, to be appointed by the College of Physicians and the Society of Apothecaries, in such proportions as they may think fit; supplemental Examiners not exceeding one-fourth of the ordinary Examiners to be appointed in each of the subjects of examination, to act in place of ordinary Examiners disabled by illness or otherwise; the supplemental Examiners in Surgery and in Anatomy and Physiology to be appointed by the College of Surgeons, and those in the other subjects by the College of Physicians and Society of Apothecaries, in such manner as they may think fit.

UNIVERSITY INTELLIGENCE.

UNIVERSITY OF OXFORD.

RADCLIFFE TRAVELLING FELLOWSHIP.—The examination for this Fellowship will begin on Tuesday, February 9th, in the medical department of the museum.

PHYSICAL SCIENCE SCHOLARSHIPS.—On Tuesday, February 9th, an examination will be held for at least two Physical Science Junior Studentships, of the value of from £85 to £100 *per annum*, and tenable for five years from the day of election.

BEQUESTS TO LIVERPOOL CHARITIES.—Mr. R. L. Jones, timber-merchant, of Liverpool, has left the bulk of his property to the charities of Liverpool, which will, it is expected, benefit to the extent of about £325,000. The deceased gentleman was a partner in the firm of Jones, Bland, and Co., one of the oldest firms connected with the Liverpool timber trade.

REPORTS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, JANUARY 5TH, 1875.

Sir W. JENNER, Bart., K.C.B., M.D., F.R.S., President, in the Chair.

Diseased Kidney.—The report of the Morbid Growths' Committee on Mr. LUCAS's diseased kidney was read. The kidney, which measured six inches by three, was lobulated and uneven in its surface. At its lower end was a cavity formed from dilated calices. The upper end was but slightly altered, and the ureter was unchanged. In the middle of the kidney was a mass about an inch across, consisting of the normal elements of kidney structure. As the cavity was approached, the kidney tissue was gradually lost and merged into the usual material of scrofulous disease of the kidney.

Aneurism of the Mitral Valve.—Dr. WICKHAM LEGG exhibited two cases of aneurism of the mitral valve; the one at an early stage, the other more advanced. He regarded the term aneurism as of doubtful applicability, but preferred it to the term hernia. One aneurism was on the smaller flap of the mitral valve; the other on the larger. Both were the result of ulcerative endocarditis. They both pointed into the auricle from bulging during the ventricular systole. The smaller one occurred in a patient, aged 54, who came into St. Bartholomew's Hospital with bronchitis, and the *rûles* quite obscured all heart-sounds. The larger occurred in a man, aged 22, who came into hospital for rheumatism. There was a double murmur heard at the base: it was aortic. Then a mitral presystolic murmur, with a thrill, appeared, and the diastolic aortic murmur disappeared. Embola followed in the left cerebral and brachial arteries.—The PRESIDENT asked if syphilis were present in these cases.—The answer was, in both.

Hypertrophied Bursa Patellæ.—Mr. NUNN showed a hypertrophied bursa patellæ from a female, aged 50, who had suffered from enlargement of the patella in early life from bruises. It became of the size of a moderate mamma. The case did well after removal by operation. The enlargement was due to fibrous thickening of the envelope.

Disease of the Musculi Papillares.—Dr. BURNEY YEO exhibited a morbid mass involving the musculi papillares of the left ventricle (a recent specimen). The man in whom it was found was brought to King's College Hospital on the preceding Friday in a cab, and on his arrival was found to be dead. At the inquest, it was found that he had suffered for some time from attacks of dyspnoea with fainting. There was no other morbid change in the body, except a small tubercle in one lung. The morbid growth involved two or three of the musculi papillares; it was one inch and three-quarters in length, and an inch in breadth. It grew from the apex of the ventricle. It did not interfere with the closure of the mitral valve. There was some dilatation of the ventricular cavity, but there was no valvular disease. The aorta contained several small atheromatous patches. The man was twenty-seven years of age. On microscopic examination, the mass was found to consist of rounded cells, with fibrillæ.—The PRESIDENT inquired if there were any syphilitic scars.—Dr. YEO replied that there was none. The heart-tissue was merely flabby.—Dr. CAYLEY had met with a case, where the growth was in the wall of the left ventricle. There was a history of syphilis.—Dr. GREENFIELD related a case of growth in the right ventricle, where there was no history of syphilis.—Dr. DOUGLAS POWELL asked if any clot was entangled in the mass.—Dr. YEO answered that he could not tell, as he was not present at the *post mortem* examination.

Epithelioma of the Colon.—Mr. NUNN brought forward a case which occurred in an old gentleman, aged 75, who had enjoyed excellent health up to a week of his death. When seen he was moribund, with his abdomen collapsed. The skin was covered with small sessile warts. On *post mortem* examination, an extreme contraction of the bowel was found, so complete that a No. 3 catheter would scarcely be admitted.—In answer to several questions, Mr. NUNN said that there were no symptoms in life, and no examination with the microscope made.—Mr. MAUNDER asked if the bowels were found loaded at the necropsy.—Mr. NUNN replied that there had been fecal vomiting for a week.

Complete Cancerous Occlusion of the Rectum.—Mr. BRYANT brought forward this case. It occurred in a girl, eighteen years of age, who was under his care for seven weeks, when colotomy of the ascending colon was performed. The girl made a good and quick recovery. A month before her death, she went to bed from sheer debility, and sank. The rectum was found to be so completely occluded that not even a hair would pass. There were several tubercles in the peritoneum. Under the microscope, the mass was found to contain cellular elements amidst fibres. He thought the mass cancerous. The principal

point of interest in the case was the perfect occlusion.—In answer to a question from the PRESIDENT, Mr. BRYANT said that the symptoms were those of occlusion and not of cancer. The organs were all sound; and there had been no dysentery.—Mr. THOMAS SMITH asked if the feces were easily retained in colotomy of the ascending colon.—Mr. BRYANT said that they were fairly so. There was no history of syphilis.—Referred to Morbid Growths' Committee.

Extreme Ulceration of the Rectum cured after Colotomy.—Mr. BRYANT showed a specimen, which had been handled until it had been torn. The patient, a female, aged 24, came into Guy's Hospital on August 29th, with a narrow stricture of the rectum. The bowel narrowed up to it. There were several fistulæ through which passed feces. The suffering was so great that an operation was determined upon. The patient rallied well, and the pain was relieved. Nine weeks after the operation, a finger could be passed into the stricture, and the ulcerations were cured. Nineteen weeks afterwards, acute suppuration of the hip-joint set in, which proved fatal. The patient had had syphilis. Mr. Bryant thought that if the hip-joint disease had not come on, the patient might have lived to the ordinary length of days.—Mr. CHRISTOPHER HEATH felt some surprise that the bowel had not been narrowed by the cicatrization of the ulcerated surfaces.—Mr. BRYANT answered that ordinarily such was the case, but that here the contraction was very slight. This formed his reason for bringing the specimen forward.

Internal Stricture, with Rupture of Cæcum.—Dr. WAY exhibited the specimen. The patient, two hours before death, felt intense pain, and also experienced a sensation of something giving way. The cæcum had ruptured without any evidence of previous ulcerations. The bowels were somewhat misplaced. The stricture consisted of a mass of scirrhus. In the channel through which the feces passed, there was a vegetable seed of the size of a pepper-corn.—The PRESIDENT said that he had paid much attention to so-called seeds in the bowels, especially in the appendix vermiformis, and always found them to consist of fecal and calcareous matter. He should like to know the results of a microscopic examination of the body.—Dr. HILTON FAGGE remarked that it was a fact that the rupture always occurred away from the point of stricture.—Mr. HOWARD MARSH gave a case in point.—Referred to Morbid Growths' Committee.

Overdistension of Bowel from Umbilical Hernia.—Mr. BRYANT gave some details of a case of overdistension of the bowel from a small umbilical hernia. Death resulted from rupture.

Votes of Thanks to the retiring officers followed, to which Sir WM. JENNER briefly replied, and the meeting adjourned.

CLINICAL SOCIETY OF LONDON.

FRIDAY, JANUARY 8TH, 1875.

PRESCOTT HEWETT, F.R.C.S., President, in the Chair.

Subcutaneous Urthrotomy.—Mr. TEEVAN exhibited a patient, aged 31, upon whom he had performed this operation. The man had suffered from a severe stricture for seven years. Six years ago, he had some form of extravasation, which necessitated his entry into Charing Cross Hospital, where the abscess was opened and a catheter passed into the bladder. Three years ago, he came under Mr. Teevan's care for a tight stricture, complicated with a fistula and occasional attacks of retention. By gradual dilatation with soft bougies, the stricture was enlarged to 7, English gauge, and the fistula cured. As dilatation could not be carried beyond the size mentioned, the patient was taught to pass a No. 5 bougie for himself, inasmuch as a larger instrument always set up irritation and made him worse. After three years' absence, the man again came under Mr. Teevan's care last October, complaining that, for the three years he had been away, he had never gone longer than three days without an attack of retention, and was often obliged to pass the bougie six times a day. It was clear, then, that the bladder was not at fault, for a bougie always sufficed to relieve the retention. Continuous dilatation and various remedial measures having utterly failed to cure the patient of his repeated attacks of retention, Mr. Teevan on November 16th subcutaneously divided the stricture, which was situated in the centre of the perineum, and was three-fourths of an inch long, on a grooved catheter-staff, with a sliding catheter. A fine tenotome was used for the operation. The shoulder of the sliding staff having been clearly made out, the skin was pierced in the *raphe* of the perineum, and the tenotome inserted into the slit in the catheter-staff and run along to its end; the mucous membrane and stricture being afterwards divided with a sawing movement. No anæsthetic was given, and not more than a dessert-spoonful of blood was lost. The urine drawn off was very slightly tinged with blood. Mr. Teevan apprehended the patient would have rigors, as he had previously been attacked with them, and he, therefore, tied in the elastic catheter

and gave the patient ten-grain doses of quinine just to demonstrate the inutility of those stock remedies, and to show that American surgeons were right in their views regarding the retention of a catheter after operation. Twenty hours afterwards, a rigor occurred, and the catheter was withdrawn. The puncture was healed in forty-eight hours. The after-treatment consisted in passing a large olivary elastic catheter every third day, and the patient left St. Peter's Hospital quite well on December 3rd, holding his water for six hours, passing a good stream, and not having had an attack of retention since the operation. Mr. Teevan remarked that the case imperatively called for operation, as the patient could not follow his avocation. He had selected this particular operation as he considered it specially indicated in the present instance. External urethrotomy would have been a severe procedure, as there was neither abscess nor fistula. He discarded the splitting operation, as that method was the most fatal of all urethral operations, and was followed by speedy and aggravated relapses. There remained, then, only internal urethrotomy and subcutaneous section, and he preferred the latter, as he knew he could by it completely divide the stricture, which encased the urethra like an iron hoop. He stated, that he believed he was the first surgeon who had ever divided a stricture in this country on a catheter staff, with a slit in it for the knife to run along. He drew attention to the fact that scarcely any scar was visible at the point of operation.

Mr. HULKE thought sufficient time had not yet elapsed since the operation, to judge of the patient's future condition. He was open to correction, but he certainly thought he had seen Sir W. Fergusson use a catheter-staff over twenty years ago, for division of a stricture; he himself had also used one.—Mr. MAC CORMAC asked for further particulars as to the operation; whether the mucous membrane was cut; and if the operation was strictly a subcutaneous one; whether there was any fear of extravasation, and if a catheter tied in the bladder after the operation would not be likely to prevent such an accident.—Mr. TEEVAN, in reply, said he was confident that the man would have a relapse unless an instrument were passed from time to time. In all cases of stricture, relapses occurred after every operation, unless the dilatation was kept up, by the passage of an instrument from time to time. He could now, at the end of a month, pass as large a catheter as before the operation; the period of relapse was more deferred than with other operative methods; the operation also occasioned the minimum amount of danger. Sir W. Fergusson, he believed, had never used a catheter-staff with a slit in its convexity for the knife to run in. The great advantage of the catheter-staff was, that it drew off the urine before the operation, so that the operator knew beforehand that he was cutting in the right direction. The instrument was first used by a surgeon in New York; the literature of this country did not mention it. The wound was to all intents subcutaneous, for, although a small puncture was made with the tenotome in the skin of the perineum, and the instrument then divided the mucous membrane and stricture together, yet, immediately upon its withdrawal, the external opening was closed with lint, and at once healed. Infiltration might occur after any urethral operation, but it was almost unheard of; he had tied in a catheter simply to show that it would not prevent rigors.

Fibrous Nasopharyngeal Polypus.—Mr. HOLMES related a case of the kind occurring in a man admitted, at the age of 27, into St. George's Hospital, in May 1866. The tumour was removed by excising the whole of the upper jaw-bone, except its orbital plate, and tearing away the polypus from the base of the skull, where it was found to spring from the sphenoid or basilar process of the occipital bone. The operation was performed without chloroform. It was perfectly and rapidly successful. The patient, who had been exhausted by constant hæmorrhage, immediately revived, and was very soon at work again. In about a year, a like epistaxis again took place, but did not prove formidable till two years ago (six years after the first operation). He was readmitted into St. George's Hospital in November last, and, as the growth was found to be growing rapidly into the nostril, it was removed by opening up the old cicatrix; still without chloroform. He was well enough to go out in a week, and had not since suffered from hæmorrhage. The growth first removed was found to consist almost entirely of fibrous tissue, with a few fibre-cells intermixed. The recurrent growth had the same composition, but was looser in texture; the cells were in rather larger proportion and some of them were rounded. Microscopic sections of both were exhibited. The author remarked on the tendency to recurrence which such tumours possessed; on the easy access which was afforded by the removal of the upper jaw (leaving, however, its orbital portion) to the base of the skull from which the tumour grew; on the convenience of this method in case of recurrence, as was well illustrated by this case; and, finally, on the greater safety and facility of operating without chloroform, whenever the patient could bear the operation.

Mr. CALLENDER said that eight years ago he had removed a tumour from the wall of the nostril, close to the aperture by which it communicated with the antrum. He removed the greater part of the superior maxilla, leaving the orbital plate. The patient recovered and went again to the country, where, after five years or so, the growth returned. It was again removed by Mr. Callender, who, in scraping the bones to take away all the diseased parts, went as far back as the bodies of the vertebrae. Both these operations were performed under chloroform. After the second operation, the woman was again sent to the country. The latest intelligence reported that she was dying; and Mr. Callender believed she had since died. He feared the disease might recur in Mr. Holmes' case, and at each recurrence prove to be more and more malignant, and eventually fatal to the patient's life.—Mr. BARWELL was sorry to be obliged to concur in Mr. Callender's gloomy views of this case. He feared, also, that the disease would spread farther and farther, and become more malignant at each return. As regarded the position from which these growths proceeded, he had once removed the superior maxilla in operating upon a case of the kind, and then felt that the tumour came from the body of the sphenoid bone, of which he took so much away that he feared to go farther lest he might implicate the brain. He saw the patient for the next year or two, and then lost sight of her for thirteen years. She then brought to Mr. Barwell her child, which was suffering with a nævus of the soft palate and pharynx. Such a nævus was very rare. Did it have any hereditary connection with the mother's disease?—Mr. CROFT had operated upon such a case as that of Mr. Holmes in 1871. The polypus sprang from the position which Mr. Callender had described in his case—the outer wall of the nostril, close to the antrum, whence it projected back into the pharynx. Mr. Croft made an incision along the ala of the nose, then carried it outwards, reflected the skin, exposed the anterior surface of the superior maxilla, reflected the periosteum, cut away the denuded bone from the anterior wall of the antrum, and then excised the growth. Through the window in the bone he could see all the parts quite up to the base of the skull. He might have removed a tumour from the base through this limited opening, had it grown from such a position. The periosteum, being relaid, re-formed bone within two months after the operation, and no deformity was present. The mass removed was a spindle-celled sarcoma. It recurred; but Mr. Croft had not pressed any further operation upon the patient.—Mr. HULKE remarked that Nélaton's method of splitting the palate gave every opportunity for the removal of small growths. He did it by two methods. Sloughing and deformity were apt to follow. Mr. Hulke had had three cases; in two of which the disease sprang from the posterior part of the nares. He would always advise the operator to save the roof of the mouth, if it were possible.

Subperiosteal Excision of the Os Calcis.—Mr. HOLMES exhibited a case concerning which he intended to speak at a future meeting.

Hæmoptysis in a Syphilitic Patient.—Dr. FARQUHARSON read notes of the case. The patient, a strong, well-built soldier, was admitted into the Coldstream Guards' Hospital, on August 10th, 1874, under the care of Surgeon-Major Trotter, who kindly allowed the case to be brought forward. During the previous April, he had been sixteen days under treatment for condylomata; but, although the cicatrix of the primary sore could readily be detected, no special history could be obtained of its nature or treatment. Three weeks before his present admission, he had begun to complain of cough and dyspnea, and had expectorated tenacious mucus, latterly mixed with blood; but, on the above date, a careful physical examination of the chest, could detect nothing abnormal. He had not lost flesh, but his aspect was rather anxious, and his face sallow and cachectic, and a syphilitic element being suspected, he was at once put upon twelve grains of iodide of potassium, and one drachm of liquor hydrargyri bichloridi, twice a-day. The symptoms continued at first unchecked, consisting of a very frequent, hard, irritable cough, followed by the expulsion of sputa, intimately mixed with dark blood, but not attended by constitutional disturbance, nor abnormal physical signs. On the eighth day, however, marked improvement was noted; and on the nineteenth, he was discharged from hospital, and had since continued in perfect health. The case seemed of interest in connection with others of a similar nature observed by Mr. Trotter, and in all of which the same train of symptoms occurred in connection with a venereal taint. The records of syphilitic diseases of the lung were chiefly pathological, and various authors had described with much fidelity the appearances observed, but clinical opportunities of tracing the early symptoms had been but rarely met with. In the present case, it seemed improbable that gummata could have been deposited in the lung; but the opinion was hazarded that mucous tubercles might have been thrown out on the delicate lining membrane of the ultimate pulmonary tissue. The gradual oozing of blood, consequent on the congestion and rupture of capillaries, and its prolonged contact with the minute bronchi or air-

cells, brought about the excessive lung-irritation observed, and had this not been checked, serious degenerative changes would probably have taken place. The true nature of the case, however, having been suspected from the first, specific treatment was attended by a perfectly successful result.

Dr. CAYLEY inquired if there were any trouble, such as ulceration, about the larynx, for there might be ulceration of the larynx without loss of voice or hoarseness. He should rather be inclined to the view that, as there was an absence of physical lung-symptoms, the disease in this case was in the larynx.—Dr. SOUTHEY remarked that hæmoptysis occurring, as in this case, in the course of syphilis, was not rare. The source of the blood was doubtful. Without previous complaint, the patient would have a sudden bad cough, and then came the blood, which, as Dr. Farquharson had said, was not frothed. The physical signs were simply loss of vesicular murmur over one part of the lungs. The hæmorrhage, Dr. Southey thought, was due to vesicular extravasation; and probably a thrombus of a pulmonary vein in some part existed.—Dr. BUZZARD inquired into the state of the patient's temperature, and said that it had been shown that, if a high temperature fell under the use of iodide of potassium, it would go far to prove that the case was one of syphilis.—Dr. FARQUHARSON thought the blood looked much more as if it had come from the lung than from the larynx. It was mixed with mucus, as if it had come after prolonged coughing.

SPECIAL CORRESPONDENCE.

EDINBURGH.

[FROM OUR OWN CORRESPONDENT.]

Election of Infirmary Managers.—Antiseptic Properties of Chloral Hydrate.—Mortality in Edinburgh.—Large Number of New Buildings.—The Mammalian Ovary and Ovum.

THE meeting of Infirmary contributors, which I mentioned last week, was a particularly lively one, the mode of election of the six managers being the disputed point. The Lord Provost, as chairman, ruled that one set of six must be put up against the other, and that it was not feasible to vote for each name individually. This greatly displeased the supporters of the ladies, and there is some talk of the matter being brought before the Court of Session. To prevent any similar confusion in the future, it has been determined that at these annual elections the names of all intending candidates shall be sent in at least a week sooner than the day of election, and a printed list of all candidates is to be handed to each voter as he comes into the meeting, so that he may indicate upon it the names of the candidates for whom he wishes to vote. This is a sensible arrangement, and will probably prevent any legal proceedings being taken in the matter.

A further experiment has, we hear, been tried with chloral-hydrate solution, as a test of its antiseptic properties. Two or more bodies belonging to the University dissecting-room were injected with it, instead of with the ordinary preservative solution. The result was satisfactory; entirely so as regards the skin and muscles; not quite so good with the internal organs. Should further experiment prove that the solution answers the purpose as well as spirit or other preserving agents generally in use, it will certainly be a considerable saving of expense.

The mortality of the city, which was 38.43 per 1000 of estimated population last week, has risen to 44.25 in the week just ended, and is still attributable almost entirely to the very unusual prevalence of chest diseases, induced by the severe weather from which we have lately been suffering. To add to our miseries, a severe epidemic of influenza has been passing over the town for some time past, not adding materially to the loss of life, but affecting health and comfort very considerably. From fever generally the deaths are 35 out of a total of 175 deaths from all causes—this includes 15 from scarlatina, and 5 from diphtheria. One sad case is much talked of, where three children died of the last-named disease within a week, in a house in one of the best and most healthily-situated terraces in town.

For the past few months the pockets of the charitable have been seriously bombarded from many sides at once, for contributions for building purposes. Indeed, the present time is marked by the unusual number of new buildings which are in course of construction, or in embryo, in connection with medical or scientific work. The University new buildings, for which the plans have just been sent in, the New Infirmary, a hospital for incurables, a new maternity hospital, a new and enlarged medical missionary dispensary, in place of the old one in the Cowgate—these are surely enough to tax all our energies before they are completed. It is, from one point of view, unfortunate that they are all endeavouring to push forward their claims at once; but at

all events it shows a vast amount of energy and enterprise on the part of the promoters of medical charities.

At a recent meeting of the Royal Society, Dr. Foulis read an elaborate paper on the Structure and Development of the Ovary and Ova in Mammalia. The paper was the result of an independent investigation of the subject on which Dr. Foulis has been engaged for the past two years. On some points his conclusions were different from those commonly received by anatomists. He holds that the so-called tubes of the ovary are really depressions, resulting from the outward expansion of the adjacent parts through the development of ova. He also concludes, from his observations, that the tunica granulosa of the ovum is formed, not of epithelial corpuscles, as many suppose, but of cells developed in the stroma of the ovary. Another point, on which he laid stress, related to the theory of cell-development. Dr. Foulis attributes a much more important part in the multiplication of cells to the division of the nucleus, than has of late been assigned to it. The paper was illustrated by many beautiful microscopical preparations and drawings, and is to be followed by another, on the pathology and pathological anatomy of the ovary, to be read before the Medico-Chirurgical Society at its next meeting. We understand the papers will shortly be published in one of the journals.

MILITARY AND NAVAL MEDICAL SERVICES.

MOVEMENTS OF ARMY MEDICAL OFFICERS.—Deputy-Surgeon Prendergast is taken on the strength of the Aldershot division from December 30th, as principal medical officer.—Surgeon Major Murphy has been ordered from the School of Military Engineering at Chatham to Dublin for duty early next month.—Surgeon-Major Comyn has been ordered to proceed in the *Euphrates* to Bombay.—Surgeon H. P. Brown has arrived at Ballinrobe and assumed medical charge of the detachment of the 2nd Battalion 17th Regiment.

OBITUARY.—The late Mr. R. J. O'Flaherty, C.B., Surgeon-General of the British Medical Department in the Bombay Presidency, whose demise took place last month at Bombay, joined the British Medical Service in 1835. He joined the army at Scutari in the beginning of 1854, as sanitary officer to the force there. He accompanied the army to Varna, and was appointed to the medical charge of the Heavy Cavalry Brigade. He went to the Crimea with the brigade, and, after the battle of Balaklava, was appointed to take charge of the transport which conveyed the wounded officers and men to Scutari, where he remained in charge of the General Hospital. While there, he received the thanks of the Duke of Cambridge when his highness visited the hospital, as well as those of other high military and medical officers. For his services, he received a Companionship of the Bath, medal with clasp, and the 5th Class of the Medjidie. He was appointed second medical officer to General Ashburner's Chinese Expedition in 1857, and, on the outbreak of the mutiny, was transferred to India. He arrived in December 1857. In 1858-59, he was with the Malwa Field Force under Sir John Michel. After the suppression of the mutiny he returned to England, and was appointed Surgeon-General in October 1872.

MEDICAL NEWS.

MEDICAL VACANCIES.

THE following vacancies are announced:—
ARMY MEDICAL DEPARTMENT—Surgeons. Applications to be made to the Director-General of the Army Medical Department.
ATHY UNION, co. Kildare—Medical Officer and Public Vaccinator. Salary, £120 and fees.
BAKEWELL UNION—Medical Officer for the Bakewell District and Workhouse. Salary, £25 and £46 per annum respectively.
BECKETT HOSPITAL AND DISPENSARY, Barnsley—House-Surgeon. Salary, £140 per annum, with furnished rooms, gas, and coals.
BIRMINGHAM AND MIDLAND FREE HOSPITAL FOR SICK CHILDREN—Acting and extra-Acting Physicians. Applications not later than February 3rd.
BIRMINGHAM GENERAL DISPENSARY—Resident Surgeon. Salary, £130 per annum, with furnished apartments, coals, light, and attendance. Applications on or before the 20th inst.
BLACKBURN UNION—Medical Officer for the Harwood District. Salary, £25 per annum.
BRIDGWATER UNION—Medical Officer for No. 2 District. Salary, £70 per annum.
CASTLE WARD UNION—Medical Officer for the Ponteland District. Salary, £20 per annum. Also, the Workhouse. Salary, £30 per annum.
DEBYSHIRE GENERAL INFIRMARY—Assistant House-Surgeon. Food, lodging, and washing, but no salary. Applications to Secretary.
EMSWORTH—Certifying Factory Surgeon.

ESSEX LUNATIC ASYLUM—Second Assistant Medical Officer and Dispenser. Salary, £100 per annum, with board, lodging, and washing.

FIFE AND KINROSS DISTRICT ASYLUM—Assistant Physician. Salary, £80, with board, etc. Apply to Dr. Fraser, Medical Superintendent, Cupar-Fife.

GRAVESEND and MILTON UNION—Medical Officer for the District of Milton, and Workhouse. Salary, £85 per annum, and fees. Applications to be sent in on or before the 20th instant.

HARRIS, Parochial Board of—Surgeon. Salary, £66 per annum, including vaccination and medicine for the poor. The gentleman elected will get £90 per annum for attending the ratepayers and cottars within South Harris. Applications to be made to the Chairman of the Parochial Board of Harris.

HEADINGTON UNION—Medical Officer for the Wheatley District. Salary, £70 per annum.

HULL GENERAL INFIRMARY—Dispenser. Salary, £75 to £100 per annum. Election will take place on the 28th instant.

HOSPITAL FOR WOMEN, Soho Square—Surgeon and Assistant Physician.

INDIAN MEDICAL SERVICE—Twenty appointments as Surgeon. Examination in February 1875.

KILCHRENNAN and DALAYICH, Parochial Board of—Medical Officer. Salary, £60 per annum. Applications, on or before the 30th instant, to W. J. B. Martin, Riccarton, Lochgilphead.

LEEK UNION—Medical Officer for the Endon District. Salary, £200 per annum.

LICHFIELD UNION—Medical Officer for the Alrewas District. Salary, £35 per annum.

LOCHMAEN, Parish of, Dumfriesshire—Medical Officer. Salary, £50 per annum, and fees. Testimonials to be lodged with the Inspector of Poor on or before the 16th instant.

MIDDLESEX LUNATIC ASYLUM, Hanwell—Assistant Medical Officer.

MITFORD and LAUNDITCH UNION—Medical Officer for the Workhouse. Salary, £45 per annum.

NORTH BRIERLEY UNION—Medical Officer for the Seventh District.

NORTH-EASTERN HOSPITAL FOR SICK CHILDREN, Hackney Road E.—House-Surgeon. Salary, £100 per annum, with attendance, rooms, coals, and light.

OKHAMPTON UNION—Medical Officer for No. 1 District. Salary, £35 per annum. Applications to be made on or before the 22nd instant.

PLYMOUTH UNION—Medical Officer for No. 3 District.

POPULAR and STEPNEY SICK ASYLUM DISTRICT—Assistant Medical Officer to the Asylum.

REDDITCH and DISTRICT MEDICAL ASSOCIATION—Medical Officer. Salary, £150 per annum, with fees and unfurnished house.

ROYAL FREE HOSPITAL—Junior House-Surgeon.

ROYAL INFIRMARY FOR WOMEN and CHILDREN, Waterloo Bridge Road—Physician.

ROYAL UNITED HOSPITAL, Bath—Resident Medical Officer. Salary, £100 per annum, with board and lodging.

ROYAL EDINBURGH HOSPITAL FOR SICK CHILDREN—Assistant to the Extra Physician. Salary, 50 guineas per annum—Resident Medical Officer. Applications to be made on or before the 20th instant.

RYDE DISPENSARY—Physician.

ST. BARTHOLOMEW'S HOSPITAL—Assistant Physician.

ST. LUKE'S HOSPITAL FOR LUNATICS—Second Clinical Assistant. Board and furnished apartments.

ST. MARY'S HOSPITAL, Paddington—Resident Registrar. Salary, £100 per annum, with board and residence.

ST. MARLEBONE GENERAL DISPENSARY—Physician Accoucheur. Applications on the 10th instant.

ST. MARY'S HOSPITAL—Resident Registrar. Salary, £100 per annum, with board and lodging.

SHEFFIELD PUBLIC HOSPITAL and DISPENSARY—House-Surgeon. Salary, £120 per annum, with board, lodging, gas, and washing.

SMALLEGHURGH UNION—Medical Officer for the Ludham District. Salary, £52 14 per annum.

STRAFORD-ON-AVON UNION—Medical Officer for the Welford District and Workhouse. Salary, £50 per annum.

STRATHKINNESS, Village and District of—Medical Officer. Salary, £10 from Parochial Board, with £10 from a workmen's club, exclusive of midwifery fees. Apply to Mr. A. Cowper, Kincaid, Cupar-Fife.

TENDRING UNION—Medical Officer for the First and Second Districts. Salary, £17 per annum.

TORPHINS in the Parish of Kincardine O'Neil, Aberdeenshire—Parochial Medical Officer. £45 per annum. Applications to Chairman of Parochial Board.

TRINITY COLLEGE, Dublin—Professor of Chemistry. £200 per annum, and fees. Applications to the Rev. Dr. Haughton, Trinity College.

TYNEMOUTH UNION—Vaccination Officer.

UNIVERSITY COLLEGE HOSPITAL—Resident Medical Officer. Applications not later than February 1st.

UNIVERSITY OF EDINBURGH—Additional Examiner in Medicine.

WEST WARD UNION—Medical Officer for the Patterdale District.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

BLAKE, J. H., appointed Surgeon to the Islington and North London Provident Dispensary (Hornsey Branch).

POWELL, G. B., F.R.C.P.E., appointed Resident Medical Officer of the Nottingham Friendly Societies' Medical Institution.

SATL, W. Wingate, M.D., appointed Surgeon to Her Majesty's Gaol at Lancaster Castle, the J. Pearson Langshaw, F.R.C.S., resigned.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3d., which should be forwarded in stamps with the communication.

DEATHS.

•**HEALEY, Edward, M.R.C.S.E.**, of Lister Street, Hull, aged 79, on January 9th.

•**STEELES, J. Daniel Wells, M.D.**, at White House, Linsworth, Leics., aged 48, on January 7th.

OPERATION DAYS AT THE HOSPITALS.

MONDAY Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

TUESDAY Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

WEDNESDAY St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

THURSDAY St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

FRIDAY Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.

SATURDAY St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—East London Hospital for Children, 2 P.M.—Hospital for Women, 9.30 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M.—Royal Free, 9 A.M. and 2 P.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY.—Medical Society of London, 8.30 P.M. Mr. Maunders's Second Lettomanian Lecture, "On Wounds and Haemorrhages; also, on the Use of the Antiseptic Catgut Ligature".

TUESDAY.—Pathological Society of London, 8.30 P.M. Mr. Wagstaffe: Papilloma of Tongue. Mr. Sydney Jones: Congenital Dislocation of both Hips (living specimen). Mr. Sydney Jones: Lymphangioma secreting Chyle (living specimen). Mr. Sydney Jones: Hypertrophy of Limb from Disease of Knee-joint (living specimen). Mr. Hulke: Epithelioma. Dr. Hoggan: Microscopical Specimens of Sarcoma in Cod. Dr. Hoggan: Microscopical Specimens of Cancer prepared by a new Process. Dr. Dowse: Invaginated Intestine. Dr. Dowse: Syphilitic Disease of Rectum. Dr. Pye Smith: Enlarged Liver and Spleen without Leukæmia. Dr. David Pearson: Cancerous Breast and Liver. Mr. Cripps: Fatty Degeneration of Muscles of the Leg. Dr. Gowers: Ulcer of Stomach. Dr. Greenfield: Contraction of Coronary Artery; Obstruction of Renal Artery; Fibroid Disease of Heart.

THURSDAY.—Harveian Society of London, 8 P.M. Mr. H. W. Kinnlmark, "On a Case of Cancer of the Liver".

FRIDAY.—Quekett Microscopical Club, 8 P.M. (University College). Mr. T. Charles White, "On the Aquarium as a field for Microscopical Research".—Clinical Society of London, 8.30 P.M. Mr. T. Holmes, "Notes of a Case of Subperiosteal Excision of Os Calcis". Dr. Thorowgood and Mr. Bywater Vernon, "A Case of Optic Neuritis, with complete Loss of Vision—Recovery under Treatment". Mr. Pugin Thornton, "A Case of exceeding infrequency of the Pulse".

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with Duplicate Copies.

AUTHORS desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor: those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

DR. DODGSON.—We are unable to assist our correspondent in the matter. We know of no other medical man who has tried them.

THE WORTHING INFIRMARY.

We very much regret to see that the embroglio at the Worthing Infirmary has increased, owing to the ill-advised action of a small meeting of five gentlemen, who appear to have treated Dr. Goldsmith with studied discourtesy. Without entering into details, which are of considerable complication, we shall only say, that we heartily hope that Dr. Goldsmith will be re-elected for the sake of the cause of infirmary management. The management of the Worthing Infirmary has been admittedly bad, and the reforms which Dr. Goldsmith advocates are such as, we think, every well-wisher of the Worthing Infirmary ought to desire to see adopted. We are heartily glad to see Mr. Cleveland Smith's manly and generous-minded circular, and we trust that no one will be found who will attempt to slip in past Dr. Goldsmith, and so to undermine his professional brother in an undoubtedly righteous contest for useful reforms.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

THE SCOTCH POOR-LAW MEDICAL SYSTEM.

SIR,—I beg to ask your advice in connection with the following circumstances. I commenced to attend a girl suffering from typhoid fever ten days ago. When I intimated the nature of the case to her sister, with whom she stays, she made application to one of the bailies of the town to get assistance from the Board. The bailie communicated with the officials of the parish to which the girl belongs, and in the meantime gave the necessary assistance from his own parish. The girl had never formerly required parochial relief, and as soon as possible after her recovery will provide for herself. There is no medical officer here appointed by the Board; but a pauper may go to any medical officer when in trouble, and the Board will refund the doctor to the extent of five shillings *per annum* for each pauper he may have to attend.

Now, I think five shillings quite inadequate remuneration for attending a case of typhoid fever, and would feel obliged if you would advise me in the manner I ought to act in such a case. Surely, £1 rs. would be a small enough fee for having to attend a case of serious illness for three weeks or a month. I shall look for an answer in this week's BRITISH MEDICAL JOURNAL, and am, etc.

January 5th, 1875.

A NEW MEMBER.

* * The New Member has our hearty sympathy in the case which he has put before us; but we fear that, having attended the girl whose case he cites without, as it appears, any authority from any one to do so, he must be content to take from the parochial authorities just that which they may be disposed to give, even though it may be limited to that wholly inadequate amount which Scotch liberality defines as a sufficient honorarium for attendance on the necessitous sick. Bad as the English system of medical relief undoubtedly is, so far at least as the country is concerned, that existing in Scotland is infinitely worse. The Committee on Scotch Poor Relief, of which Mr. Crawford, ex-M.P., was Chairman, in their report, recommended that the Irish system of dispensary medical relief should be introduced; and subsequently Mr. Crawford brought in a Bill embodying such recommendations. Unfortunately, that gentleman aimed at too much, and his Bill was thrown out on the second reading; but we learn, on the authority of the present Lord Advocate and others, that this occurred on no point connected with medical relief, on which subject there existed a general concurrence of opinion, that something ought to be done.

ONE of the latest novelties in the way of charms for watch-chains and guards consists of a piece of linen caustic tastefully mounted. It is supposed to combine the *utile* with the *dulce* to the wearer, who, immediately he or she has been bitten by a rabid animal, applies the handsomely mounted piece of caustic (perchance a souvenir), and brings the charm of poetry into common life whilst burning out the part bitten by a dog or cat.

A MEDICAL ADVERTISER.

THE following is taken from the *Hull News* of December 26th, 1874.

"Medical Dispensary (private), open daily (Sundays excepted), Brook Street (Prospect Street end). Professional consultations: Morning, 9.30 to 11; Evening, 7 to 8.30. Fees.—To the Artisan and Mechanic Classes: Advice and Medicine, 2s.; to the Labouring and Poor Classes: Advice and Medicine, 1s. At the Dispensary only, and within the above-named hours. Midwifery Engagements. Vaccination of the children of private patients only every Tuesday afternoon at Three o'clock. Physician, Surgeon, and Accoucheur, E. H. Lincker, F.R.C.S.E., L.R.C.P. Lond., M.R.C.S. and L.M.R.C.S. Eng., L.S.A. Lond., etc., registered, late Medical Officer in H.M.'s Public and Military Service, etc. (Successor to the late Dr. Brownridge.) Private Residence, 16, Spring Bank.

Dr. W. E. FORSTER, M.P. for Bradford, having been requested to lecture on behalf of the Local Hospitals, replied that he did not feel able to comply with the wish of the constituents; but he could not allow the Hospital Fund to suffer from this cause, and enclosed a cheque for £50 in consequence.

IS THERE ANY FORM OF SMALL-POX OF A NON-CONTAGIOUS CHARACTER?

SIR,—I shall be glad if you or any of your readers can supply an answer to the above question. We have been visited in this town of late by an epidemic of small-pox, imported some four months since. The Local Board of Health have erected a hospital, where patients are received, nursed, and attended, at great expense to the locality. Recently the rector, who had been most assiduous in his pastoral ministrations to those suffering from the complaint, was laid up and died. The practitioner in attendance certified that his death was caused by "varicella sine eruptione". The Local Board and other public bodies were anxious to pay respect to their late esteemed minister, and many visited the corpse, which lay in state for five days; but on the promulgation of the above "cause of death," great anxiety was caused among all classes; and the other medical practitioners were of opinion that if such were the cause of death, it was not right that a public funeral should take place, but that every precaution should be taken for the public welfare. However, the following certificate, which I extract from the local paper, was affixed to the church-door, with the signatures of two medical men attached to it.

"We hereby certify that the late Rev. — died from small-pox poisoning, and herewith add that his illness was not in the least degree infectious."

What we want to know—for I write with the concurrence and for the information of others as well as myself—are these forms of small-pox, viz., *varicella sine eruptione* and small-pox poisoning, non-infectious? I cannot find any such nice distinction in any of the books of reference at hand.

For obvious reasons, I do not mention the name of the town, but enclose my card as a guarantee of good faith. I am yours, etc., CARBOLIC.

Dr. J. M. A. TUTOR, AND H. BIRMINGHAM.—The officials of the College of Surgeons will only be too glad to relieve your anxiety, and that of the 350 candidates, by sending you the result of the recent Arts Examination as soon as the report has been received from the College of Preceptors. There are many hundred papers on the several subjects to be read by the examiners.

AN INSURANCE QUERY.

ARE there any instances in which qualified medical men have taken an agency for Life Assurance Companies? What is the opinion of the profession on the subject? Is the proceeding considered compatible with professional dignity?

"INSURANCE."

NOTICE TO ADVERTISERS.—Advertisements for insertion in the BRITISH MEDICAL JOURNAL, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than *Thursday*, twelve o'clock.

MR. CHUBB (Torpoint).—Under such circumstances, it is customary and proper to make a separate charge.

DR. J. M. CHROMBIE's letter shall appear next week.

TO SUCH STRANGE USES MAY WE COME AT LAST.

THE following paragraph appears in the *Irish Times* of December 23rd.

"The Earl Street Medical Hall.—The Earl Street Medical Hall, conducted by Messrs. J. Leonard and Co., has, within the last two years, taken a leading position amongst the medical establishments of the city. The late Mr. John King, of 19, North Earl Street, established there an extensive drug-hall, in which he did a large business as a chemist and druggist, and the Messrs. Leonard, having become possessed of his interest, have since successfully conducted the business which he had previously carried on, with the addition of a compounding department, managed by efficient assistants, under the immediate supervision of Dr. Leonard. The medical department, which forms one of the principal features of the establishment, and to which the utmost attention is paid, is in charge of Dr. Leonard himself, who has had large general practice since the period of his connection with the Richmond, Whitworth, and Hardwicke Hospitals. In what may be called the mercantile department, there is a display of every variety of goods usually found in a medical first-class drug-hall: pomades, hair-washes, creams, perfumes, caskets, bouquets, hair-brushes, toilet-soaps—all of the best quality. Amongst the specialties of the establishment are King's Spanish onion pomade and Spanish onion hair-wash, which have been highly esteemed as toilet requisites, and of which Messrs. Leonard and Co. are sole proprietors and manufacturers. It need only be added, that the Messrs. Leonard are determined that their establishment shall maintain the reputation which it has already achieved, and that it shall be found in every respect calculated to meet the wants of the large and important district in which it is situated."

X. Y. B.—Dr. Laidlaw Purves, Guy's Hospital; Mr. Dalby, St. George's Hospital; and Mr. Field, St. Mary's Hospital.

MEDICAL DEGREES AND TITLES.

SIR,—The great body of general practitioners have been hardly used by recent changes in the regulations for qualification as compared with the old system. A student of twenty or twenty-five years ago found that the Apothecaries' Society's license was a *sine qua non* to confer a legal right to practise; and M.D.s of Scotland could not legally practise their profession, and recover fees, in England and Wales. One has even heard of threats of prosecution against them for practising unlawfully. Under these circumstances, it was not surprising that men felt themselves compelled to go to the "Hall"; and they voluntarily went to the College of Surgeons, to the neglect of the Scotch Universities, which were altogether outside the pale of English law. All this was very anomalous, and is now properly changed; but I think that long ere this something ought to have been done to affiliate the general practitioner, who was the victim of circumstances, to some medical college on the *ad eundem* principle. Moreover, at the time to which I refer, degrees were only sought for by pure physicians, and they would have been considered a bar to general practice. The present fashion of M.D.-general practitioner is a hybrid of recent birth. The degree of M.D. is not a fixed quantity, but ranges, through a wide scale, from high honour to the utmost disrepute. Many degrees are no higher, and some a great deal lower, than the Apothecaries' license. It is not reasonable to concede the same even nominal status to a degree obtained after prolonged residence, great expense, and high standards of examination, and to others conferred after a curriculum not longer, and tests not higher, than those of the Hall. I leave out of account the *purchase* "honour". Most surgeons must know of instances of men, before the late Acts, practising without any qualification under the wing of some qualified, perhaps absent, practitioner, until a stir was made. Then the gentleman's face was missed for a time, and he returned from some refuge for incompetence dubbed with the degree of M.D., or he obtained what some of your correspondents call the "coveted distinction" without any change of air and scene. In almost all towns, the positions of distinction and repute are quite as much held by plain Mr.s as M.D.s, sometimes more so; and to many such men the drawback to the title of Doctor would be the dubious merit of their *confrères* in its possession. The present state of things is a relic of medical barbarism; and something ought to be done, similar in principle to the College of Surgeons' early fellowships conferred upon surgeons of definite age and standing, to remove the injustice. You have recently said that, as a general rule, a man's qualifications remain what they are when he leaves Lodon; and no doubt this opinion is quite accurate. If time permitted, the general practitioners could very well compete with young doctors, some of whom, according to the testimony of your own pages, do not know measles when they see it, although in theory they have taken honours. To the busy practitioner, the loss of time puts it out of the question, and he will not purchase; so some other remedy must be found, or he must remain a victim to an injustice which is discreditable to the profession and subversive of its best interests.—I remain, Sir, December 17th, 1874. AN ASSOCIATE OF TWENTY-FIVE YEARS STANDING.

SIR,—I am very glad to find that the subject of the above title is being discussed in your columns. I have long been desirous of procuring an expression of opinion on it by the profession; and with that object in view, I put it, three or four years ago, on the agenda paper of the annual meeting of the South-Eastern Branch of the Association, but yielded to the persuasion of an old and highly valued friend and member of the Council to abstain from bringing it forward. I have regretted it ever since, but feel now that probably it is a matter which may be better and more calmly discussed in the JOURNAL, than *vis à vis* at a meeting.

It appears to me that all the letters which have yet appeared on the subject have failed to deal with that which is the very first point to be settled, viz.—What is the title "Dr.," and what is its significance? In my opinion, it is the ordinary colloquial abbreviation of the title "medicine Doctor" (M.D.), which is a degree granted by an University to its graduates; to whom *only* does it properly belong, and who *alone* have the right to assume it. Undoubtedly, a license to practise medicine (wheresoever obtained) cannot confer the right. Licentiate simply obtain a certificate or testimonial to the effect that they have passed a certain examination, and that they are qualified to do certain things. But they acquire no other right; they have no part or lot in the corporation or college that grants the license; they gain none of its privileges; and, when once in possession of the license, are utterly ignored by it, even when they wilfully and plainly neglect to observe all the conditions on which it was granted.

I have no sympathy with the proposition that, after so many years of practice, every medical man should be entitled to apply to the Universities, and obtain the degree of "M.D." after a sufficient examination. I have been M.R.C.S. Eng. and L.S.A. for very nearly thirty years, and I am quite content to remain as I am so far as titles go. After twenty-five years of practice, a man's opinion will be sought for, if it be worth having, without the accidental aid of any further title; and, if it be not so esteemed, no mere title will give it additional value.

I was much struck by some passages in a letter, which appeared in the *Edinburgh Medical Journal* of last month, from Dr. J. H. Balfour, on quite another subject, which have a marked bearing on this matter, and which, with your permission, I will transcribe. He says, "a degree of M.D. is higher than a diploma, mainly in the fact that the *preliminary and scientific* requirements" (the italics are his) "are, or ought to be, higher. The degree is not a mere qualification to practise, but is an University honour. It is not essential for practice, and no one need take it, unless he choose to assume a higher position than a mere practitioner. We look to our graduates as men who are to advance science, and who, in many cases, are to be the leaders of scientific expeditions." In another place, he says, "I desire to stand up for the *honour* of an University degree, and not to put it on the same level as the diploma of a College."

I am rejoiced to think that a larger proportion of the licentiates disapprove of the assumption of the "Dr.," and do not use it. And I do not, for one moment say, or suppose, that all those who dub themselves "Dr." that is, in my mind, a very grave point of the offence—they *dub themselves*—and have not waited for it to be accorded to them by the profession, are wilfully and consciously guilty of a dishonest act; I do not believe that they have ever looked at it in that light. But I cannot do other than believe that they assume that which does not belong to them, but which obviously is the right of quite another class of men. And I think further that, as honourable men, now that the matter has been put plainly before them, and the mind of the profession clearly expressed, they are bound to resign the title at once, one and all. It seems to me the only manly and straightforward course, and I hope that they will forthwith adopt it.

I am, Sir, yours faithfully,

Maidshead, December 17th, 1874.

WILLIAM HOAR.

SIR.—The subject of "Medical Titles" being again to the front, I take the liberty of troubling you with a letter. I was very glad to see the matter treated in a leading article, and hope it may lead to a solution of the enigma.

I think there is a general feeling that London has failed in its duties in not offering to the general practitioner the means of obtaining his degree. The College of Physicians sells a man a diploma which he is told is of no use to him; it was even tried to smite him on the other cheek by denying him the right to the title of the College—to call himself physician.

The proposition I would submit is, that all who have, or shall have, a diploma of a College of Physicians (such diploma entailing a separate and distinct examination from the conjoint Board) shall, on producing it for registration, have the degree of M.D. conferred upon him by the General Medical Council.

Doctor of Medicine of Great Britain is a title that would interfere with no existing privileges. The M.D. of London would be just as much valued by all who have the time, the talent, and the money to try for it. The same may be said of other universities.

The Colleges of Physicians would benefit, their diplomas being more sought after, and the degrading feeling of taking money without giving, or even offering, anything in return, would be spared them; they would be able to regard their licentiates as legitimate, and worthy of being recognised, instead of bar-sinisters in their escutcheons, to be kept out of sight as much as possible.

That the General Medical Council should give the degree, I think would be right. It is supposed to represent the profession throughout the kingdom, and therefore recognises all colleges. The gentleman who registered would feel that he was really receiving something at last for his money, and regard the Council with feelings of respect, which, I fear, few are at present able to do.

I am, Sir, yours faithfully,

D. M'D.

Dorset, December 25th, 1874.

SIR.—I was very pleased to see your leading article in the *JOURNAL* of last week referring to medical titles. I quite agree with you that some British University should make an opening for those senior practitioners who may desire to take the degree of M.D. I am a L.R.C.P. Edin. of ten years' standing, and have taken the title of "Dr." ever since I held the license. I am most willing to submit to a most searching practical examination for the M.D. degree, if I can find an University that will admit me. I am forty-three years of age, and am entitled to be admitted to examination at St. Andrew's, but find that I may be compelled to wait perhaps two or three years before there may be a chance, and then I have fifty guineas to pay for the degree. I trust, Sir, something may be done to enable senior practitioners, who may desire it, to obtain a degree from some British University, and not compel them to go on to the Continent to obtain a degree there. I enclose my card, and am, Sir, your obedient servant.

December 25th, 1874.

L.R.C.P. EDIN.

SIR.—Were it not for your article in last week's issue, I should have written in reply to M.D.'s letter, published December 17th. He seems to have given the matter very little thought. Your powerful advocacy of our cause cannot but be a source of gratification to all who are anxious to obtain the degree of M.D. from a British University, but I would venture to make one or two remarks further upon the matter. It seems to me not quite fair towards the L.R.C.P.s in actual practice, who have not spent four winter sessions at a medical school, to be degraded from taking their degree if they can pass the examination for it. Respecting the examination itself, it appears to me that in some subjects it should be very thorough, as much so as at the London University, but in others less so. I would mention pathology, medicine, midwifery, forensic medicine, therapeutics, etc., among the former; but the same knowledge of anatomy, I think, should not be required of us who have been several years in practice, as from a student at fresh from the dissecting room. It must be presumed that they have sufficient knowledge to be safe practitioners.

Notwithstanding your advancement of our cause, it seems to me that, unless we *do*, those practitioners who wish for the degree take some step, in petitioning the University, it will be a long time before we obtain what we desire. I would propose that, as early as possible in the ensuing year, a meeting be held in London—say Willis's Rooms—where the matter may be set fairly on foot, and the necessary petition drawn up. Should this proposition meet with approval, through your *JOURNAL*, the most convenient time for the meeting to be held could be easily arranged.—I am, Sir, your obedient servant,

December 25th, 1874.

A COUNTRY PRACTITIONER.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the *BRITISH MEDICAL JOURNAL*, should arrive at the Office not later than 10 A.M. on Thursday.

H. D. S.—Perhaps, the roll of the College of Physicians by Dr. Munk may give the desired information. Sir Stephen Fox, father of the first Earl of Ilchester and of the first Baron Holland, married a daughter of Mr. Whitte, one of the King's (Charles II.) chirurgeons.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Birmingham Daily Gazette; The Western Daily Press; The Manchester Guardian; The Ulster Advertiser; The Sussex Coast Mercury; The Broad Arrow; The Surrey Advertiser; The Bedale and Northallerton Times; The Hackney Express; The Liverpool Porcupine; The Scotsman; The Liverpool Mercury; The Glasgow Herald; The Stroud News and Gloucestershire Advertiser; The Bradford Observer; The Morpeth Herald; The Portsmouth Times; The Western Daily Press; The York Herald; The Sheffield Evening Star; The Brighton Guardian; The Sussex Daily News; The Wrexham Advertiser; The Newton Directory; The Sussex Coast News; The Berkshire Chronicle; The Hull News; The Southern Times; The Worthing Intelligence; The Hampshire Telegraph and Sussex Chronicle; etc.

COMMUNICATIONS, LETTERS, ETC., have been received from:—

REPORT

OF THE

COMMITTEE OF THE BRITISH MEDICAL ASSOCIATION TO INVESTIGATE THE ANTAGONISM OF MEDICINES.

By JOHN HUGHES BENNETT, M.D., F.R.S.E.,
Chairman and Reporter.*

GENERAL CONCLUSIONS.

THE general results obtained from the investigations detailed in the preceding report are the following.

I. As to the Antagonism between Strychnia and Chloral Hydrate.

In this investigation, one hundred and fourteen experiments were performed.

1. After a fatal dose of strychnia, life may be saved by bringing the animal under the influence of chloral hydrate.

2. Chloral hydrate is more likely to save life after a fatal dose of strychnia, than strychnia is to save life after a fatal dose of chloral hydrate.

3. After a dose of strychnia has produced severe tetanic convulsions, these convulsions may be much reduced both in force and in frequency by the use of chloral hydrate, and consequently much suffering saved.

4. The extent of physiological antagonism between the two substances is so far limited, that (1) a very large fatal dose of strychnia may kill before the chloral hydrate has had time to act; or (2) the dose of chloral hydrate must be so large in such a case to antagonise the fatal dose of strychnia, that there is danger of death from the effects of the chloral hydrate.

5. Chloral hydrate mitigates the effects of a fatal dose of strychnia by depressing the excess of reflex activity excited by that substance; while strychnia may mitigate the effects of a fatal dose of chloral hydrate by rousing the activity of the spinal cord, but it does not appear to be capable of removing the coma produced by the action of chloral hydrate on the brain.

II. As to the Antagonism between Sulphate of Atropia and Calabar Bean.

In this investigation, one hundred and fourteen experiments were performed.

1. Sulphate of atropia antagonises to a slight extent the fatal action of extract of Calabar bean.

2. The area of antagonism is more limited than even Dr. Fraser has indicated in his paper on the subject.

III. As to the Antagonism between Hydrate of Chloral and Calabar Bean.

In this investigation, thirty-one experiments were performed.

1. Hydrate of chloral modifies to a great extent the action of a fatal dose of extract of Calabar bean, mitigating symptoms and prolonging life.

2. Hydrate of chloral in some cases saves life from a fatal dose of extract of Calabar bean.

3. If hydrate of chloral be given before extract of Calabar bean, so that the animal is deeply under the influence of hydrate of chloral before it receives the extract of Calabar bean, the symptoms produced by the latter are much modified, and life is saved from the effects of what would otherwise be a fatal dose.

4. Chloral hydrate is of little service as an antagonist to extract of Calabar bean, if given some time after the latter. If the symptoms of the action of Calabar bean be in full operation, it will not save life, however it may modify symptoms.

5. The antagonism is limited—

a. By the amount of dose of the extract of Calabar bean—more than a minimum fatal dose of extract of Calabar bean destroying life, notwithstanding the administration of chloral hydrate.

b. By the interval of time between the administration of the two substances. There is a great probability of saving life in those instances in which the animal is under the influence of chloral hydrate before the subcutaneous injection of the extract of Calabar bean; there is less probability when both substances are given simultaneously; there is still less if the chloral hydrate be given from five to eight minutes after

the extract of Calabar bean; and no chance at all if the chloral hydrate be given eight minutes after a fatal dose of extract of Calabar bean.

6. Even in cases in which a fatal result follows the action of the two substances, the physiological effects of extract of Calabar bean are considerably modified by those of hydrate of chloral.

IV. As to the Antagonism between Hydrochlorate and Meconate of Morphia and Calabar Bean.

In this investigation, forty experiments were performed.

Hydrochlorate and meconate of morphia in no way antagonise extract of Calabar bean.

V. As to the Antagonism between Sulphate of Atropia and Meconate of Morphia.

In this investigation, eighty-one experiments were performed on rabbits and dogs.

A. In Rabbits:

1. Sulphate of atropia is physiologically antagonistic to meconate of morphia within a limited area.

2. Meconate of morphia does not act beneficially after a large dose of sulphate of atropia, for in these cases the tendency to death is greater than if a larger dose of either substance had been given alone.

3. Meconate of morphia is not specifically antagonistic to the action of sulphate of atropia on the vaso-inhibitory nerves of the heart.

4. The beneficial action of sulphate of atropia in cases of poisoning by meconate of morphia is probably attributable to the action which the former substance possesses of contracting the blood-vessels, and thus diminishing the tendency to cerebral and spinal congestion produced by salts of morphia.

B. In Dogs:

Sulphate of atropia modifies the physiological action of meconate of morphia, and may even save life after a fatal dose of the latter. The limit, however, is so narrow as to be of no practical service.

VI. As to the Antagonism between Tea, Coffee, Theine, Caffeine, Guaranine, on the one hand, and Meconate of Morphia on the other.

In this investigation, one hundred and seventeen experiments were performed.

1. Theine is antagonistic to meconate of morphia, inasmuch as the action of the one substance modifies that of the other, and may even save life from a fatal dose of either substance.

2. Meconate of morphia delayed the appearance of the convulsions characteristic of the action of theine; but, on the other hand, theine, if given in large doses, did not affect in a marked degree the action of meconate of morphia, because symptoms of poisoning by theine were soon manifested.

3. Further experiments on cats showed that, (a) while a cat may recover from the effects of a dose of 1½ grains of meconate of morphia given alone, it will not recover from the effects of a dose of 2 grains, even although the effects of the latter dose are modified by those following the introduction of 4 or 5 grains of theine; (b) that in three cases the animals recovered from the effects of 1½ grains of meconate of morphia and 4 to 5 grains of theine, while they died when the same dose of meconate of morphia was administered eight days afterwards; (c) that, when the dose of theine was increased beyond five grains, the animals invariably died, apparently from the effects of theine.

4. Experiments on rabbits, as to the antagonism between meconate of morphia and theine, were found to be unsatisfactory as regards the purposes of this inquiry, because both drugs produce epileptiform convulsions in these animals.

5. The results obtained in investigating the action of caffeine and guaranine as antagonists to meconate of morphia were similar to those observed with reference to theine.

6. Experiments were made on dogs to ascertain the effects of strong infusions of tea and decoctions of coffee as antagonists to meconate of morphia. These were unsatisfactory, chiefly because the tea or coffee was usually vomited so soon as to prevent the possibility of the exercise of any physiological antagonism. At the same time, it was observed in several instances that the administration of tea or coffee so excited the animals as to prevent them from falling into stupor or coma after a dose of meconate of morphia, which would have produced this effect had the tea or coffee not been given.

VII. As to the Antagonism between Extract of Calabar Bean and Strychnine.

In this investigation, thirty experiments were performed.

Although the symptoms produced by either substance were modified considerably by the action of the other, there was no instance of recovery from a fatal dose.

* Concluded from p. 866 of the JOURNAL for December 26th.

VIII. *As to the Antagonism between Bromal Hydrate and Atropia.*

In this investigation, thirty-six experiments were performed.

1. There is a distinct physiological antagonism between bromal hydrate and atropine.

2. After a fatal dose of bromal hydrate, the introduction of atropia arrests excessive secretion from the salivary glands and mucous surfaces of the lungs, and thus obviates the tendency to death from asphyxia caused by the accumulation of fluids in the air-passages. Atropia also causes contraction of the blood-vessels, and thus antagonises the action of bromal hydrate, which causes dilatation of these vessels by paralysis of the sympathetic nerve.

3. While atropia may save life after a fatal dose of bromal hydrate, the converse apparently does not hold good, as we have never succeeded in saving life after a fatal dose of atropia by the subsequent injection of bromal hydrate.

In concluding this report, I feel it to be necessary to allude especially to the labours of two members of the Committee—viz., first, Dr. Alexander Bennett, who completely worked out the physiological actions of cocaine, theine, caffeine, and their allied compounds; and, secondly, Dr. McKendrick, on whom the bulk of these researches ultimately devolved, and by whom the lengthened investigation on the antagonism between the sulphate of atropia and meconate of morphia was carried out. To him also we are indebted for the remarkable discovery of the antagonism between bromal hydrate and atropia. The long survey into which I have entered can convey no adequate idea of the many hours spent in laborious toil; of the skilful manipulation, sustained power of observation, judgment in inventing and comparing the results of experiments, and, I may add, patience under failures, which have characterised the efforts of these gentlemen. Even the account of the investigations themselves, with the tabulated results of the experiments, can give only a feeble conception of the laboratory work accomplished. The preparation of the report and its careful revision was in itself a work demanding no small time and labour.

I venture, however, to say that such are the toils and sacrifices required by modern medicine, if it be sincerely desired to solve existing difficulties, and prosecute those new inquiries which are so necessary for maintaining its position as a science and as an art. I sincerely trust that no parsimony nor error in administration will restrain the British Medical Association from continuing the noble efforts it has commenced, and rewarding by liberal grants the arduous labours of men who will dedicate themselves to these pursuits. It is gratifying to know that the present and, it is to be hoped, the future flourishing state of its finances, will enable it to take a lead in this patronage of scientific and practical endeavour for the benefit of humanity. I shall always esteem it a proud distinction for myself that I first indicated at least one method in which this could be accomplished,* and have demonstrated, in the two reports I have had the honour of laying before the Association, on the one hand, how error may be corrected,† and, on the other, how new fields may be acquired for the therapist in neutralising poisons and extending our means for the cure of disease.

CASE OF IDIOSYNCRASY.

THE following curious case of idiosyncrasy came under my notice lately. Mrs. R., aged 35, widow, a person of somewhat spare habit and active disposition, informs me that, since her early childhood, she has had a very strong aversion for *potatoes*. She knows no reason for this aversion; certainly it is not due to any fanciful notion. It is the result, apparently, of a peculiar idiosyncrasy. When she was quite a little creature, her uncle was very fond of playing a trick on her by concealing a small morsel of potato in a bit of butter, and inducing her to take it. The result always was *very severe vomiting*. She remembers her mother being very angry with her uncle on the occasion when he indulged in this practical joke. If she happened to be present where potatoes were being cooked, she became quite faint; and, until within a few years back, she could not even handle the tubers. At present, she would rather take the vilest medicines than taste a potato; indeed, she could not bring herself to do the latter. It is rather singular, that throughout life Mrs. R. has displayed an extraordinary susceptibility to febrile and "catching" diseases. Thus she states that, in her early childhood, she had whooping-cough, measles, scarlet fever, and since then small-pox, typhus fever, rheumatic fever, enteric fever, and lastly relapsing fever. Since suffering from relapsing fever, she has experienced some dyspnoea after exertion, and recently she had hæmoptysis.

DESCRIPTION

OF A

NEW PORTABLE THERMO-ELECTRIC APPARATUS
FOR MEDICAL AND PHYSIOLOGICAL
INVESTIGATIONS.*

By J. S. LOMBARD, M.D.,

Formerly Assistant Professor of Physiology in Harvard University, U.S.

ALTHOUGH many important facts regarding the general temperature of the body in disease have been ascertained of late years by the application of thermometers to clinical purposes, yet little or nothing has been done in the study of the temperature of different portions of the surface of the body as affected by morbid conditions of the internal organs. The reason of this is, undoubtedly, that it is only with thermo-electric apparatus that investigations of this kind can be properly made, and up to the present time all such apparatus has been of a nature to preclude its general employment by medical men. The writer has endeavoured, in the instrument to be described (see fig. 1), to combine portability and compactness with sufficient delicacy for all clinical and many physiological investigations. He believes that a very little practice will enable any one to use the apparatus with ease and accuracy. Portions of the apparatus are not new, having been devised by the writer in 1866, and described by him in *Archives de Physiologie*, July 1868.

The instrument may be divided into five parts—the galvanometer; the rheostat; the two thermo-piles; a tin kerosine lamp; and a brass stand, with a horizontal arm having a clamp at its end. Added to these are a compass and a magnifying glass. A board, three-tenths of an inch in thickness, and exactly fitting the interior of the box in which the apparatus is contained, with just sufficient allowance to permit of its being slid out at a door in one end, forms a second or false bottom to the box. The galvanometer, rheostat, lamp, and stand, are all on this board. The levelling screws of the galvanometer rest in holes in the board, and the rheostat also is secured to it. Calling the end of the box in which the door is the *front*, we have (fig. 2) from before backwards, on the left, first, the ebonite base of the rheostat, four and two-tenths inches from left to right, and three inches from front to back; second, the galvanometer, four and four-tenths inches in diameter at its base. On the right, we have, first, the tin kerosine lamp; and, second, the brass stand. This completes the description of the arrangement of that portion of the apparatus which is on the board.

Both the galvanometer and the rheostat can be removed from the board; but it is not intended that they should be, except in case the mercury cups of the rheostat are to be emptied. In experimenting, the board, bearing on it the galvanometer, rheostat, lamp, and stand, is simply slid out at the door of the box; and the lamp and stand having been removed, the galvanometer and rheostat remain on the board as permanent fixtures.

The Galvanometer is constructed as follows. It has a circular wooden base, the levelling screws of which rest (as before mentioned) in holes, or rather depressions, in the false bottom of the box. On this wooden base is screwed a square plate of ebonite, with rounded corners, so as to clear the groove in the wooden base in which the glass shade rests. On the plate of ebonite is fastened the frame on which the wire of the galvanometer is wound. The frame is one and nine-tenths inches long, one inch wide, and one and one-twentieth inches high. It does not stand in the centre of the ebonite plate, but at one side. Placing the board (fig. 2) so that the rheostat is to the front, facing us, and, therefore, the galvanometer to the rear, the frame stands on the left hand edge of the plate (the observer's left hand), its length being from before backwards: the wire of the coil runs, therefore, in the same direction.

From each side of the frame two flat brass stanchions rise, converging towards a point over the centre of the slit in the coil, until at a height of two and one-tenth inches they are united by a brass platform, three-tenths of an inch square. On this platform is a brass cylinder, three-tenths of an inch high, covering the platform, with the exception of its four corners; and again on the cylinder, in the centre, is a split tube two-tenths of an inch long. Both cylinder and platform are pierced by a hole of the diameter of this split tube. In the split tube, and through the cylinder and platform, there slides a second tube with a milled head, and to the milled head inside this second tube is fastened one end of the fibre of unspun silk, which forms the suspension of the

* The instrument is made by William Ladd and Co., 11 and 12, Beak Street, Regent Street, London.

needles, presently to be described. The attachment of the fibre to the milled head is made by passing the fibre through a small hole in the milled head, and then inserting into the hole a little wooden plug, by which the fibre is firmly clamped.

The so-called "needles" are made on the principle of those in the galvanometers of Sir William Thomson, consisting of two light flat pieces of steel, not quite half an inch long and three-twentieths of an inch in breadth. They are joined, with opposed poles, by a slender rod of aluminium. The upper needle is purposely magnetised the more strongly of the two, so that the system remains in, or nearly in, the meridian, the north pole of the upper needle pointing north. The upper needle is pierced at its centre by an aluminium wire, which constitutes the "index" of the galvanometer. The length of this wire, on the

split tube of brass through its centre, and this split tube slides with slight friction on a brass rod six inches long, ending at one extremity in a cap with one side split, which cap fits over the milled head and brass cylinder before mentioned, resting on the uncovered corners of the brass platform. A hole in the top of the glass shade of the galvanometer permits the passage of the cap. The magnet is four-tenths of an inch wide, and the distance between its poles is three and three-tenths inches. When in the box, the magnet and rod are secured to the inside of the door.

The Rheostat is constructed on the plan of a larger one devised by the writer in 1866, and described, with figures, in the *Archives de Physiologie*, July 1868. At the left hand back corner of the ebonite block forming the base of the rheostat (fig. 2) are two binding-screws, in which

Fig. 1.

right hand side, is two and three-tenths inches. It gradually tapers to a fine point, and is blackened at its end. On the left hand side the wire projects only eight-tenths of an inch; and, therefore, to establish equilibrium, this end is much thicker than the other. The axis of the index is thus at right angles to that of the needles; and, on account of the length of the index, deflections of the needles—too slight to be observed directly—can be easily detected. On the ebonite plate, on the right hand side, is placed the scale, which consists of an arc of wood, covered with a similar arc of cardboard, graduated, resting on two brass pillars, which are screwed into the ebonite. The scale is graduated to 40 deg. on each side of the 0°; but the brass stanchions prevent the index from going farther than 30 deg., and in actual work the scale is not used above 25 deg., as beyond this point the proportionality between the degrees of the scale and the forces impelling the needles ceases. Up to 25 deg., however, the error is so slight that it may be neglected. Each degree of the scale is divided into halves; and as it is easy to read between the halves even with the naked eye, we can read to quarters of a degree. The object of the magnifying glass is to facilitate this reading. Our scale of 25 deg. is therefore divided into one hundred parts. The only portion of the galvanometer which remains to be described is the regulating magnet. This magnet, which is somewhat curved (the convexity of the curve being upwards when the magnet is adjusted), has a

are fixed the ends of the two wires coming from the galvanometer. On the front of the ebonite base are three more binding-screws, numbered 1, 3, and 2, from left to right; and at the right hand back corner is another binding-screw, marked 4. Nos. 2 and 4 are both on the right hand side of the base, in opposite corners, and are connected by a stout piece of copper let into the under side of the base. A similar connection joins Nos. 4 to the right hand of the two binding-screws which receive the terminals of the galvanometer; hence Nos. 2 and 4 are connected with each other, and with one end of the wire of the galvanometer. As regards the other two binding-screws, Nos. 1 and 3, the disposition is different. Immediately behind these binding-screws is a row of five mercury cups, cut out of the thickness of the ebonite base. At each end of the row of cups is a small brass pillar, which at the height of four-tenths of an inch terminates in a flat surface, from the centre of which rises a rod seven-tenths of an inch long, the lower half of which is smooth, but the other half cut into a screw. A stout ebonite bar, three and three-tenths inches long, and four-tenths of an inch wide and deep, with a hole cut in each end, connects the two pillars; the rods of the latter passing through the holes in the bar, and the flat surface of the pillars forming a support for the bar to rest upon. The screw portion of the rods projects above the upper surface of the bar; and a thumb-screw at each end, which works down firmly

on to the bar, keeps the latter steadily in place. The bar, therefore, passes directly over the row of mercury cups, its lower edge being four-tenths of an inch above the upper surface of the base. In the bar over the spaces between the cups are four holes: through these holes pass stout copper wires, with ebonite knobs on their upper ends. At a distance of seven-tenths of an inch from the knobs these wires bifurcate, forming two prongs, about four-tenths of an inch asunder, each prong dipping into a mercury cup, and thus forming a bridge from one cup to another. Of course, the three centre cups have each two prongs immersed in them, from two separate copper stems. By means of the knobs, the prongs can be lifted out and immersed at pleasure. In order to keep the prongs from falling back into the cups by their own weight

when lifted out, each copper stem has on its side a little projection, which does not prevent the raising or lowering of the prongs, so long as the projection points to the right along the axis of the bar, a small slot being cut from the holes into the ebonite on that side through which the projection passes. When, however, the prongs having been raised from the cups, the knob is turned so that the projection is no longer over the slot, the stem cannot descend, the projection resting on the bar and preventing this. The first mercury-cup on the left communicates with the left hand of the two binding-screws which are connected with the galvanometer. The communication is effected like that previously described for binding-screws Nos. 2 and 4. With the second mercury-cup (counting from left to right), binding-screw No. 1 is connected, the

C. Compass.

All currents entering at binding-screws 1 and 4 of rheostat, cause the index of the galvanometer to move north; and all currents entering at Nos. 1 and 3, cause the index to move south.

we measure from 10° C. to $21\frac{1}{2}^{\circ}$ C. Lowering the scale = 1° C., and we the third one, we throw in the resistance the deflection. Therefore measure from the scale dealt with cases in which the relative temperature at the moment of observation only was concerned. Suppose, however, we wish to make a prolonged experiment on the temperature of a part. If the unmarked pile be placed on another part of the body, it is obvious that, in an experiment of any duration, this part may alter in temperature as well as the part under observation, and hence our results may be confused. To avoid this, we use one pile only on the body, and expose the other to a constant source of heat—the current thus generated being opposed in the galvanometer to that of the pile placed on the body. It is for this purpose that the lamp and brass stand are used. The unmarked pile is fixed in the clamp at the end of the horizontal arm of the stand, the clamp being applied between the points of exit of the wires of the pile and their entrance into the binding-screws of the latter. Care must be taken that the binding-screws of the pile do not touch the brass clamp, otherwise a connection may be established across. The positive pole of the pile is connected with binding-screw No. 3, and the negative pole with binding-screw No. 4. The marked pile is connected by its positive pole with binding-screw No. 2, and by its negative pole with binding-screw No. 1. It will be seen that, thus connected, the current from the unmarked pile passes in the track of the resistance coils, while that from the marked one passes directly through the cups forming the key. We have thus two separate circuits opposed to each other. In experimenting with this disposition of the apparatus, we proceed as follows. The lamp being lighted, the stand bearing the unmarked pile is placed in front of it, the face of the pile being turned towards the flame. The marked pile is secured to the part to be experimented upon; and, after raising the knob of spool No. 3, we lower the first knob (the key) and note the position of the index. If the current from the pile on the body be the stronger of the two, the index will, of course, be to the north of 0° ; if, on the other hand, the current from the pile in front of the lamp be the stronger, the deflection will be to the south of 0° . By regulating the height of the flame and the distance of the face of the pile from the lamp, we can bring the index to 0° . Any alteration in the temperature of the part under consideration will now show itself, in the case of a rise of temperature, by a deflection north; and, in the case of a fall, by a deflection south. The object of interposing the resistance of the wire on spool No. 3, is to check the "leakage" of the current of the pile placed on the body into the circuit of the other pile. A certain portion of the current of each pile will pass through the circuit of the other, instead of through the galvanometer. In the case of the pile placed in front of the lamp, this loss is of no account; but in the case of the other pile the loss is important, and must be limited. With this arrangement of the apparatus $23\frac{1}{2}^{\circ}$ galvanometer scale = 1° C.

In conclusion, the writer would say that the instrument could have been made much more delicate, and, in fact, could have been improved upon in many ways, had he not endeavoured to reduce its cost to the lowest possible point.

CALCULUS IN URETHRA OF A CHILD.

H. SPARROW, aged 4 years, was admitted into the Home for Sick Children, Sydenham, on December 14th, 1874, with retention of urine. For several days, it appears, he had manifested symptoms of great irritability of bladder. Upon examination, there was found to be priapism, with an elongated prepuce, which was distended with urinary excretion. There was constant stillicidium urinae. The bladder was distended, and painful upon manipulation. The penis was much swollen and oedematous. The countenance was distressed and anxious; pulse frequent. My colleague Dr. Bird kindly administered chloroform, when a catheter was inserted into the preputial orifice, but could not be introduced into the meatus urethrae. The prepuce (rather than circumcision) was slit up by means of a curved bistoury, and just within the urethra was discovered a small round calculus, firmly impacted, giving rise to the retention. After passing a bent probe beyond the calculus, it was at length hooked, and ejected with a certain amount of force, causing it to fall upon the floor of the room. Its character was phosphatic. A catheter was then passed, and the over-distended bladder relieved of its contents. After the application of two sutures to the wound, the penis was enveloped in oiled lint, and the child was put to bed, when he almost immediately fell into a tranquil sleep. He is now convalescent, although not yet discharged from the Home.

STENCER T. SMYTH, M.D., F.R.C.S.,

Honorary Surgeon to the Home for Sick Children, Sydenham.

CLINICAL LECTURE

ITCH IN PRIVATE AND IN PUBLIC PRACTICE, AND ITS TREATMENT.

By TILBURY FOX, M.D., F.R.C.P.,

Physician to the Department for Skin-Diseases of University College Hospital.

GENTLEMEN,—There are certain differences in the cases of itch that come under our treatment in public and in private practice respectively, to which I wish particularly to direct your attention. By public practice, I mean such as hospital, infirmary, and Poor-law practice, amongst the poorer classes. The matter is one of practical importance to you. You know that, in describing scabies to you, I do not follow the usual method of books, and divide the disease into papular, vesicular, and pustular scabies, and so forth; but I speak of the disease as consisting in an *essential* element or lesion, the *acarus* in and with its furrow, and certain *accidental* concomitants, which result as consequences of the irritation set up, and the scratching practised for the relief of the latter; of, in fact, the acarian furrow and imbedded *acarus*, and the results of irritation. These latter vary in kind, and include hyperæmic papillæ and follicles, vesicles, pustules, and excoriations, etc. Now, in private practice amongst the better classes, the differences in cases of scabies, as compared with those observed in hospital practice, are those of *degree*, not kind, and have reference chiefly to the *accidental* concomitants, and only slightly to the *essential* lesion of scabies.

In private practice, cases are occasionally met with equal in severity to any that are seen in public practice; but, on the other hand, as the rule, they are not so severe, and the disease is not so extensive, and *very frequently in private practice instances come under observation in which the accidentals of scabies are scarcely if at all marked*. There are a certain amount of itching, and an *acarus* or two here and there, and nothing more; and such cases are often erroneously diagnosed. There are many instances of scabies only a slight shade worse; a few acarian furrows, with a few papulations.

The variations are due to several causes, chiefly to the observance of greater cleanliness, the seeking of medical advice earlier (so that the disease has not time to put on the aspect of severity), and to the better nutrition, amongst the better to do, as compared with the poor classes. Cleanliness has greatest influence, because it is a great check to the development, and migration from part to part, of the *acari*; and malnutrition amongst the poor favours the development of the pustular concomitants; and, lastly, the longer the disease lasts, the greater, of course, is the scratching. When want of cleanliness, much scratching, and malnutrition go together, the worst cases of scabies occur, and they may now and then, as I have said, be met with in private practice. But, inasmuch as private patients are more cleanly than public ones, seek advice earlier, and are well fed, scabies amongst them occurs in its least expressed form. But even when the disease has existed some time, it is surprising how slightly marked the disease is in some cases, on account of the extreme cleanliness observed, and the repeated washings practised by private patients.

It is with these slighter cases of scabies that I wish to deal specially—with those in which a solitary or a few *acari* are present, and very little else. A hasty observer may readily overlook the nature of such cases as those to which I now refer more particularly. I occasionally see instances of scabies which, at first sight, would seem to be instances of pruritus simply. There are two circumstances, however, about them, which should always put you upon your guard. The one is the seat of the pruritus—viz., the front of the abdomen, the penis, the inner and upper part of the thigh, and the front of the forearms; and the other is the occurrence of the pruritus especially, or perhaps only, at night, when the sufferer gets warm beneath the clothes. If careful examination in such cases be made, a reddish papulation may be detected along the upper line of the penis, or a solitary acarian furrow at one of the interdigital spaces or about the wrist; and this may not be readily found. I have often detected after careful search a stray furrow concealed by some of the little folds of skin in the interdigital spaces, which had escaped observation for awhile. About the forearm may or may not be a few very delicate papulations that require, for their clear detection, that the skin should be looked at obliquely. Of course I mean that, in the cases I describe, *acari* have been actually extracted from these solitary *uniculi*. There may be no eruption anywhere but on the penis, one or two acarian furrows being seated there. I have known such cases complicated by glandular swellings in the groin, and mistaken for syphilis; but, if careful examination be made,

the acarian furrows may very plainly be made out; and the swelling accompanying the furrow lacks the indurated character of a true chancre, and is clearly simply inflammatory. In these cases of very slightly marked scabies, there is mostly no concomitant aid to diagnosis; I mean, for instance, no infection of others in the same family, etc. In a somewhat more marked degree, where there are a few acari and furrows about the interdigital, or the wrists, or perhaps the penis, with a small amount of rash on the forearms and the abdomen and thighs, the disease is very common. The acarian furrows, if the persons attacked be very cleanly, may readily be overlooked again, because they are not discoloured and rendered more distinctly visible by dirt; and frequently the acari are scratched away, and only the opened up cuniculus remains; but the form or skeleton of the cuniculus is seen. A little circular area, whence the cuticle which was upraised into the vesicle is gone, is seen; and, stretching away from this, is a line marked out on each side by loose cuticle, forming at one time the walls of the now opened up cuniculus. This is practically diagnostic of scabies. The papulation, if any, in these cases, about the forearms and the thighs, is made up of hyperæmic papillæ and follicles more or less scratched. There are no acari anywhere, but about the wrists and interdigital and the upper line of the penis. In these cases, the occurrence of itching at night, and the presence of fine papules on the anterior surface of the forearm and about the abdomen and thighs, at once suggest the probability of scabies being present.

The next degree of scabies of course does not differ from that ordinarily seen in public practice. I would say, then, as regards private practice, be very careful to satisfy yourselves that scabies is not at the bottom of what at first sight appears to be pruritus, which is intensified or developed at night, and is specially seated about the abdomen, the inner part of the thighs, and the forearms or hands. I know that such cases are oftentimes scabies, but are not diagnosed correctly till the disease develops to a decidedly significant extent.

Of course, I have been speaking of the disease in adults. In the case of children, there may be no characteristic evidence of scabies about the hands, but only about the feet and buttocks. It is often difficult to detect cuniculi acari in very young children. But one very good guide is to be found in the character of the eruption. The disease most liable to be confounded with scabies is lichen urticatus. Well, that consists of wheals leaving behind papules. It may be said to be an uniform disease as regards eruption. There is no eruption besides the wheals and papulation. But in scabies the eruption is multifiform. It is papular, vesicular, and pustular. In public practice, the scabies of children is marked by complicating ecthyma, as might be expected; but this is not so common in my experience in private practice.

Turning to scabies in public practice, I have only to observe, on this occasion, that the diagnosis of scabies, as ordinarily seen, is, as the rule, very easy. But, in rarer instances, the disease is so general, and so intermingled with excoriations and pruriginous papules, etc., that it presents the aspect rather of a pruriginous eczema, or phthiriasis mixed with eczema, than a scabies, since the eruption is not confined to the usual seats of itch-rash, but attacks the parts about the shoulders, the back, the lower parts of the legs, and back of the forearm, as well. But there is one very safe guide in these cases; and that is, the history of the eruption, which shows that the latter began as scabies usually does, whilst acarian furrows will be detected, although most of them may be obscured by the free suppuration about them.

Treatment.—I have some special remarks to make in regard to the treatment of itch-cases in private and in public practice. You may very readily overtreat cases of itch in the former, for the reason that the disease is less severe, and the acari are not present over so large an area. In the mass of instances occurring in public practice, the disease exists, for the reasons I have before given, extensively over the surface, and acari have burrowed, not only about the hands, but in other parts of the body, especially the penis, the feet, the scrotum, and the abdomen perhaps. But in many cases in private practice, I mean amongst the well-to-do, the acari are only present at the interdigital spaces. Hence it is a rule of prime importance in treating itch, to accurately determine, at the outset, how far the acari have disseminated themselves about the body. The reason is obvious. There is no need to apply parasitocides to parts in which acari do not exist, because the irritation and eruption elsewhere are due to sympathetic action; and these irritated parts will get well if the acari be destroyed, and they do not require the use of irritant remedies, such as parasitocides are, but soothing remedies. The practice is to apply the remedy to every part of the body where eruption exists in cases of itch. Clearly this is wrong, from what I have just said. My rule is this: if the disease be recent, if it be only slightly marked, if it began about the hands, and there be no cuniculi about the penis, I order the parasiticide to be rubbed into the interdigital, the palm of the hand, and the wrists, and I apply a soothing

lotion to all other irritable parts of the body. If, however, there be—I am speaking of a lighter degree of disease—cuniculi about the penis as well as the hand, and especially if the disease appeared to begin coincidentally in point of time by itching about the lower part of the abdomen, then I apply the parasiticide to the hands and the penis; but even here I do not rub in the remedies very long (for three days and three mornings), and I only, for precaution sake, let the patient smear the parasiticide upon the scrotum and the thighs, and for two or three times. I then order a soap bath, a change of linen, and I expect my patient to be quite well. The absence of pruritic irritation at night on the third day I take as a good test to the cure of the disease. In no case do I use any but parasitocides of moderate strength; half a drachm of sulphur to the ounce of lard is a sufficiently strong ointment, if sulphur be the remedy chosen.

But I will suppose that a well marked case of itch comes before you in a well-to-do person. Here I recommend you not to depart from the rule I have laid down, viz., not to use your parasiticide generally to all the body, but to rub it freely in where the acari are, about the hands, the penis, and the scrotum, and to smear it gently on a few times only to the adjoining parts; to use it for three days only, and not in too great strength. This suffices to kill all acari, and the secondary results, viz., those of irritation, quickly subside. What frequently happens is, that the remedies kill the acari, but their use is persisted in longer than is necessary to effect this object, and only aggravates the already existing irritation and secondary eruption.

I repeat, then, by way of summary, that in private practice, if the disease be slight and recent, use the parasiticide to the hands only, and soothe the other parts with some emollient or astringent lotion or ointment; and, in all other cases, treat actively the hands and the parts about the genitals, but other parts only very slightly. In all cases, use remedies of moderate potency; at the end of three days leave off the parasiticide, give a soap and water bath, and see if the itching at night have ceased. If any vesicles appear between the fingers or about the wrists subsequently, these may be touched by the parasiticide. But if the latter be used for any length of time, the itching and irritation which had at first subsided, may increase, and this increase is often mistaken for an exaggeration of the itch, whereas it is that of the secondary pruritic eruption. In these cases, the skin becomes so irritable that it is a difficult matter to get it into a quiescent and healthy condition. *Overtreated cases of itch in private practice are by no means uncommon.*

I have one word to say, in conclusion, about bad cases in private and public practice, and the use of sulphur vapour-baths. In these bad cases, no doubt the acari are disseminated widely, and active treatment is needed. One remedy in common use is the sulphur-bath. I think a caution is needed as regards its use. I believe that it is abused. Though I much prefer a good soaking in a sulphuret of potassium bath, and the prescription of a mild parasiticide ointment, yet sulphur vapour-baths may be employed; but I think a single one properly administered—at most two—sufficient. I would have the patients well washed, first of all, with soap and water, and then put into the sulphur-bath. If the effect be that the pruritus at night is destroyed, I do not think it needful to repeat the bath, especially where the skin is much inflamed. You have seen, yourselves, many cases in which these baths have cured the actual scabies, but have set up a severe inflammation and pruritus in the skin that are most difficult to subdue. I never use sulphur vapour-baths in itch, on that account, except where the disease is of the severest kind, because I believe all the acari can be destroyed by simpler and less irritating applications. In these cases, the same rule holds good, I think, as in the simpler cases. It is easy to overtreat these cases. If, at the end of a few rubbings with mild sulphur or storax ointment the skin be less inflamed, less irritable, the vesicles and pustules drying up, and the patient get a good night, I consider that the itch itself is practically well, and I then treat by parasitocides the usual haunts of the acari and soothe the other parts. But there is another very important matter in these cases. It is to keep the same linen on next the skin during the use of the parasiticide, and when a change of linen is made, to disinfect all the clothes by heat. I cannot now go into the question whether the acari dwell temporarily in the clothes. They can, no doubt, live long enough off the body in the clothes to be conveyed by clothes from one person to another, and, if so, then it is important to prevent these clothes from serving as the media of re-propagating the disease, or transmitting it from the infected to the healthy.

TESTIMONIAL.—The Huddersfield small-pox patients have presented to Mr. John B. Pritchett, the medical officer of health for the urban sanitary district, a gold pencil-case and a silver goblet. On the former is engraved, "To J. B. Pritchett, with a silver goblet, from patients in the Huddersfield Borough Hospital during 1873 and 1874."

ABSTRACT OF A CLINICAL LECTURE

A NEW METHOD OF TREATING BAD CASES OF
VARICOSE VEINS OF THE LEG.*Delivered at University College Hospital, London.*By JOHN MARSHALL, F.R.C.S., F.R.S.,
Surgeon to the Hospital.

[Reported by J. W. LANGMORE, M.D. London.]

A HEALTHY looking man, aged 38, was admitted into University College Hospital on November 21st. He had been in early life a farm-labourer, but for some years past had been a railway "plate-layer". He stated that he had generally enjoyed good health, but that when he was only sixteen years of age the internal saphena vein of the left leg began to enlarge. The veins of the foot and leg were not distended first, but the vessel seemed to enlarge all the way up the limb at the same time. Afterwards the veins of the right leg became distended in the same manner, and they had been getting worse ever since. He had worn a bandage on the left leg for some years, but lately he had suffered so much pain on standing, that he had been unable to continue at his work, and had been compelled to apply at the hospital. On admission, the internal saphena veins were found to be in an extremely varicose condition on both legs; that of the left leg was especially large and tortuous, most so over the inner side of the knee and the upper part of the leg; there was a large dilatation also just below the saphenous opening.

Mr. Marshall gave a short sketch of the etiology and pathology of varicose veins. He held that the primary cause was some mechanical obstruction, some impediment to the progress of the circulation, and that this obstruction was generally situated high up in the trunk, and that even the action of the heart might be concerned in it. Generally, the enlargement began in the veins of the foot and leg and crept gradually up the thigh; but, in the case under notice, the distension of the vein in the thigh seemed to have occurred very rapidly. The enlargement at the saphenous opening was also worthy of notice; it was cases like the present which had caused some surgeons to think that the principal obstruction was at this point. Mr. Herapath used to enlarge the opening in the hope of removing the supposed impediment. But, when we had an opportunity of examining the deep veins in such a case, we found that they also were enlarged in the same manner. Alteration in the coats of the veins was a secondary change which confirmed and exaggerated the disease, but which was not itself the cause. As the result of long continued distension, the veins lost their elasticity, their coats became thinned, the muscular and elastic elements degenerated, and were replaced by simple connective tissue. The valves also became incompetent in consequence of the enlarged calibre of the vessel; and the increased weight of the longer column of blood on the lower part of the vein helped to increase the mischief.

Mr. Marshall then passed on to notice some of the chief operations which had been proposed and practised for the cure of this troublesome ailment. All operations were, of course, only palliative; they merely shifted the disease from one locality to another. Still, by a judiciously planned operation, the patient might be relieved for months or even years. The simplest mode of giving relief was by means of elastic bandages or stockings; but, if these failed, if the patient still suffered from pain when standing or walking sufficient to interfere with his ability to work, or if he were the subject of those troublesome chronic ulcers which frequently accompany this disease, then the surgeon was justified in having recourse to operative interference. The object of all the various operations which had been practised was the same, viz., to obliterate the vein; but this was not as easy as might have been expected, and consequently the operations were not always as successful as could be wished. The object, then, was to excite inflammation in the coats of the vein which should be followed by adhesion of the opposed surfaces of the inner coat, with consequent obliteration of the canal, and finally by atrophy of the vein and its contraction into a fibrous cord.

One old plan was to apply the actual cautery at intervals along the course of the vessel; but a mere burn of the skin was not sufficient for the purpose, it must go through the skin and into the vein; and this was a severe measure, often followed by diffuse phlebitis, and consequent blood-poisoning.

John Bell cut out small pieces of the vein at intervals; but this was also a severe and dangerous operation, often followed by extensive inflammation and hæmorrhage. Von Grafe used to lay open the vein, stuff the cavity with lint, and allow the wound to heal by granulation from the bottom; this was, of course, an effectual cure, but it was a tedious one, and was not unfrequently complicated by suppurative phlebitis.

The plan most commonly employed now is to obstruct the vein by ligatures placed at intervals along its course; but, unless these be placed very close together, this plan is often ineffectual; the vein is obliterated only just at the point of ligature, the intermediate portions remain patent, and the blood soon finds its way into them by means of collateral branches. To obviate this tendency, some surgeons, after placing the ligatures, have divided the vein subcutaneously between each pair; this gives more satisfactory results, but is sometimes followed by troublesome inflammation and suppuration.

The plan of treatment, said Mr. Marshall, which I have carried out on this man, and which I propose to try more extensively as opportunities offer, is not altogether new, but presents, I hope, sufficient novelty to deserve the notice of the profession. It resembles that of Von Grafe, which I have just mentioned. The grave objections to his plan were the occasional occurrence of troublesome hæmorrhage, and the risk of diffuse suppurative phlebitis followed by embolism, septicæmia, etc. The former danger might, I thought, be obviated by elevating the limb well and by carefully applying Esmarch's bandage before the operation; and the latter risk might also be avoided by the use of antiseptic dressing. The operation in this case was performed as follows. I drew with ink a straight line, six inches in length, over the course of the tortuous vein, just below the knee, where it was most enlarged. Esmarch's bandage having then been applied, I next passed a hare-lip pin under the vein at the top and bottom of the marked portion, and secured it with the usual figure-of-8 and bougie ligature. I then cut through the skin over the course of the vein, opened the vein itself just above the lower ligature, and slit it up on a director as far as the upper pin—a distance of about nine inches. But, when I had thus laid open the vessel, it struck me that the healing of the wound would probably be accelerated if I removed entirely this ragged-looking piece of useless membrane; I, therefore, cut it across at each end, and removed it by dividing some small branches. The vessel was quite empty, and no blood was lost during the operation. In performing it another time, I should, after exposing the vein, cut it through, and remove it at once without opening it. Three hare-lip pins and figure-of-8 ligatures had also been placed on the vein higher up, a little above the knee. The wound was dressed antiseptically, according to Lister's method, and a bandage applied firmly as high as the knee.

As regards the after-progress of the case, I need only remark that, on December 1st, the wound was found to be nearly healed, and the carbolic dressing was left off; it would have been better for the patient if this had been continued for a few days longer, for his recovery was somewhat retarded by a slight attack of erysipelas, which now invaded the limb. It is, however, worthy of note, that the wound in the leg healed first, and that the patient was kept in bed for some days longer solely by the state of the vein in the thigh where the pins only had been used. In this case, therefore, the two methods were contrasted on the same patient, and the part where the vein was extirpated healed first; the other went through the ordinary course of slow peri- and endo-phlebitis. It seems, therefore, that, not only is the operation of removing the vein a more certain and effectual mode of treatment, but that it is also speedier—that the more formidable looking clean cut wound thus made is, when dressed antiseptically, more rapidly cured than is the apparently trivial inflammation which is set up by the pins. In operating on another similar case, I should not hesitate to remove a much greater length of vein, even two feet, if it seemed necessary or desirable to do so.

The patient was then introduced, in order to show the result of the operation. Though dilatation at the saphenous opening was still apparent, the vein in the thigh was greatly diminished in size, and below the incision was apparently obliterated nearly down to the ankle; altogether, the state of the limb operated on presented a marked contrast to that of the right leg, which, at the time of the patient's admission, had been decidedly the less varicose of the two. He stated that he was now quite free from pain in the limb; he was wearing an elastic stocking by way of precaution, but Mr. Marshall thought that this would soon be unnecessary, and advised him to use it for the right leg.

VACCINATION.—Mr. T. L. Gentles, Medical Officer and Public Vaccinator for the South District of the Derby Union, has received a Government award of £70:6 for efficient vaccination.

DIPHTHERITIC PARALYSIS:

ITS NATURAL COURSE, PATHOLOGY, TREATMENT, AND RELATION TO PARALYTIC AFFECTIONS FOLLOWING FEVERS.*

By SIR JOHN ROSE CORMACK,

Chevalier of the Legion of Honour: M.D. Edin. and Paris; F.R.S.E.; Fellow of the Royal Colleges of Physicians of London and Edinburgh; Physician to the Hertford British Hospital, Paris; etc.

[Continued from BRITISH MEDICAL JOURNAL, December 12th, p. 735.]

I PROCEED now to illustrate the paralytic affections which occur during and after Relapsing Fever, Enteric Fever, Cholera, Typhus, Dysentery, Rheumatism, the Exanthemata, and some other diseases.

PARALYTIC AFFECTIONS DURING AND AFTER RELAPSING FEVER.

In my account, published thirty-one years ago, of the Relapsing Fever as I saw it in 1843, in the first months of that most remarkable epidemic, I mention that paralysis of the deltoid and other muscles occurred in a few cases. In a woman, aged 36, there was loss of power in both deltoids, which continued for about ten days after restoration to health had taken place in all other respects. As my fever-patients, on leaving the hospital, generally ceased to be under my observation, I had comparatively few opportunities of studying paralysis and the other sequelæ of relapsing fever. In later writings on relapsing fever, I find notices of partial paralysis having occurred during convalescence in the practice of various observers.

Dr. R. T. Lyons, of the Bengal Army, in his valuable treatise on *Relapsing or Famine Fever*, published in London in 1872, says that paralysis is more commonly associated with that fever in India than in Europe. In this opinion, he is probably correct. Possibly, however, the Indian fever epidemics which, from the published descriptions, he considers to have been epidemics of relapsing fever, were not all of that nature, using the term *relapsing fever* in the special and restricted sense in which clinicians have employed it for the last thirty years. Be that as it may, it is evident that many of the Indian epidemics in question were essentially similar in kind to well observed and accurately described European epidemics of relapsing fever. But, even supposing that the fever which we know in Great Britain under the name *relapsing*, is not the same as any Indian fever, the following extract from the work of Dr. Lyons furnishes, in a concise form, some most interesting and precise statements in proof of the frequency with which various forms of paralysis have been observed as *sequelæ* of fevers in India. Such statements strengthen the opinion that there is nothing absolutely *sui generis* in the paralysis of diphtheria.

Again, at page 148, Dr. R. T. Lyons says:

"In the Kimerdy epidemic of 1833, M'Donell met with two cases in which paralysis supervened, and in one of these there was also anæsthesia or numbness; in both, the paralysis occurred during convalescence. In the Mercara epidemic of 1842, Lawrence says that several patients experienced loss of power and sensation in the lower limbs, and walked with a tottering gait, these symptoms being sometimes preceded and sometimes followed by cedema of the feet and hands. In the Mangalore epidemic of 1845, the same author found paralysis to be a frequent complication, and he further states that convalescence from paralysis was protracted and retarded by a temporary recurrence of the earlier symptoms: whether these were increase of circulation, cedema, or febrile heat, the paralytic symptoms were always increased at the same time. Eyre met with three cases of palsy, which were mistaken for beri-beri; all these proved fatal. In one case, the paralysis occurred in the primary fever, in another during the intermission, and in the third in the relapse. In the Umballa epidemic of 1866, Bateson found one of his two cases of hæmorrhage of the bowels affected with facial paralysis. Gray likewise met with a few cases of partial paralysis in the epidemic in the Lahore Jail in 1864. Hugh Clark observed one case of dysphagia. In the *Indian Medical Gazette* for April 1867, Garden describes eighteen cases of partial paralysis in children after fever. I consider the disease, from Garden's description, to have been relapsing fever, for the following reasons. The duration of the fever from two to eight or ten is more consonant with the character of relapsing fever than of typhus or typhoid, the former, moreover, being rare in India and the latter rare in Upper India, where Dr. Garden's cases occurred. In his account of the Saharanpore epidemics of 1869-70, he states that the disease was of annual and constant occurrence in his district. It is probable that it was occasionally in 1866, in which year Garden made these observations. In the eighteen cases, paraplegia occurred in ten, paralysis of the left leg in one, of the right

wrist in two, of the left arm in one, of the pharynx in one, and paraplegia in two. All these cases occurred during convalescence. There was a natural tendency to recovery after an indefinite duration; but the more protracted cases became permanent."

Here we see two very strong points of similarity to diphtheritic paralysis: the "natural tendency to recovery" and the tendency of the "more protracted cases to become permanent". It is not inconsistent with a belief in the tendency to natural recovery to state that protracted cases sometimes become permanent; this permanence depends generally on muscular atrophy—a condition which is brought about by the paralysis, and which, acting as a new morbid cause, prevents natural recovery. A vigilant physician, with full command of his therapeutic opportunities, may often intervene, so as to prevent muscular atrophy—and its necessary consequence, permanence of the paralysis—whether its origin be diphtheria, enteric fever, or relapsing fever.

More serious than atrophy is the degeneration and destruction of muscular tissue—and specially of certain muscles—which is frequently observed after certain fevers and other diseases. That is a subject to be afterwards discussed.

PARALYTIC AFFECTIONS DURING AND AFTER ENTERIC FEVER.

After enteric fever, partial paralysis frequently supervenes. I have also met with cases of paraplegia supervening as a sequel to enteric fever. Paralysis, general or partial, is, perhaps, much more commonly a sequel of this disease than is generally supposed. Both in hospitals and in private practice, I have repeatedly seen it overlooked during convalescence, from its being mistaken for, or masked by, general post-febrile debility. Generally, the paralytic affections are limited in character, slight, and transitory. I have, however, sometimes seen them very severe and long-continued.

I subjoin the histories of two exceedingly interesting cases which I carefully observed, and reported from day to day when under my care. They were both cases in which the diagnosis was certain, and in which the fever ran a course of great severity. The first case occurred in 1870, in my military practice during the German siege of Paris; and the other was treated by me in the Hertford British Hospital in 1874. I shall afterwards succinctly describe some other cases.

CASE.—The patient was well formed, a soldier of the Garde Mobile, aged 24. He was sent into Paris on a frosty morning in December 1870, from one of the outposts, with a medical certificate to the effect that he was unable for duty, and labouring under severe dysentery. He had been, in succession, refused at four hospitals before he came to me, including two great hospitals—La Charité and the Hôpital Beaujon. At that date, all the hospitals, civil and military, and much of the extra ambulance accommodation, were overwhelmed with the sick and wounded. Both my hospitals were chiefly for wounded men; and the spare accommodation I had was being kept in reserve, in anticipation of a sortie. I, too, refused him; but, four hours after my refusal, he was returned to me with peremptory orders to receive him, as I had that day reported a certain number of beds as unoccupied. The poor fellow had been jolted about for six hours over the then rough and deeply rutted streets of Paris on a bitterly cold day. I was in my ambulance at the Ternes when he was admitted. He looked a doomed and almost a dying man; his countenance was haggard; his pulse feeble; his whole surface was cold; his respiration jerking and shallow; his shirt, great-coat, and red trousers were saturated with his alvine evacuations, which had become frozen. A small blanket in which he was wrapped was also stiff with frozen filth. From the time of his leaving the outposts till I received him, he had had only brandy and water, but of that he seemed to have had a large quantity. Two beds were forthwith prepared for him. His clothes having been taken off, he was quickly and entirely wrapped up in a large blanket wrung out of very hot water. Under this blanket, and in the recumbent position, he was carefully washed and scrubbed. After taking some beef-tea, he slept for half an hour. When he awoke, he was removed from the *vet* warm bed to one adjoining, which was dry and warm. The moving brought on vomiting, which, however, soon subsided. When I left him about nine o'clock, he had rallied somewhat, and had taken with satisfaction some tablespoonfuls of hot camphorated wine. The orders for the night were:—an astringent mixture if required; camphorated hot wine and beef-tea alternately at intervals; and turpentine stupes to the abdomen and legs. I saw him at seven next morning; he was lying on his side; his skin was naturally warm. He had had three dark liquid motions without any trace of blood. On the chest and abdomen, there was a characteristic and tolerably abundant eruption of the pink lenticular spots of enteric fever.

The case in its future progress was in all respects a typical case of uncomplicated enteric fever. In thirty days from the date of admission, he was in full convalescence. A few days later, as the

* Partly read before the Medical Section at the Annual Meeting of the British Medical Association in Norwich, August 1874.

were short of hands, he was occasionally accepted as a volunteer assistant at the surgical dressings. All seemed to be going on well till the seventh week from admission, when he complained of inability to put on his coat, which he ascribed to rheumatism. A day or two later, his gait was dragging, and the grasping power of both hands enfeebled. For ten days longer, he was able to move about the ward; but, during all that time, his locomotive power was daily diminishing. At last, he had to keep his bed, after which time the paralysis advanced so rapidly that soon he was unable to get out of bed for necessary purposes. There was paralysis of the external oblique muscle of the left eye for a week or ten days, and, on several occasions, there was atony of the bladder, requiring the use of the catheter. Notwithstanding the many disadvantageous circumstances incident to the siege, this man made a complete recovery. For several months, he remained under my treatment. At the close of the Second Siege, when the Government regained possession of Paris, he was sent to a military convalescent station in the country, whence he ultimately returned in robust health. During a great part of his residence at my hospital, the diet, from siege exigencies, was scant and bad, but supplemented largely by good red wine, which fortunately we could command in abundance. The internal treatment of this man, from the time the paralysis showed itself till it ceased, consisted in his taking fully two litres of excellent claret daily, and twenty drops three times a day of the tincture of the chloride of iron of the *British Pharmacopœia*. The external treatment consisted in the application of a succession of small blisters to the legs and arms.

It is worthy of remark, that the urine was albuminous immediately before and during the first ten days of the paralytic symptoms.

[To be continued.]

THE TREATMENT OF SYPHILIS BY MOIST MERCURIAL FUMIGATION.

By JOHN ST. S. WILDERS, M.R.C.S., Surgeon to the Queen's Hospital, Birmingham.

As a pupil, and afterwards the friend and colleague, of the late Mr. Langston Parker of Birmingham, I must ask to be allowed space to reply to the following extract from a lecture delivered by Mr. Lane, on the modern treatment of syphilis, which appeared in the *JOURNAL* of December 12th ult. "Inunction is, perhaps, on the whole, to be preferred, especially for hospital patients; but it is troublesome and dirty, and, therefore, it is often undesirable to resort to it in private practice. The same objection applies to fumigation, with the addition that it is as a rule more debilitating, for the nightly vapour bath has a decidedly depressing influence."

With Mr. Lane's remarks on inunction, I quite agree; but I venture to take very serious exception to those on fumigation. To what method of fumigation he alludes (whether moist or dry) the writer does not explain; but I presume the well-known moist mercurial vapour-bath, first used by the late Mr. Langston Parker, about 1849, is the one called in question. Now, notwithstanding the fact of Mr. Lane's twenty-three years' experience as surgeon to the Lock Hospital, I affirm with the utmost confidence that the treatment of syphilis by moist fumigation is neither troublesome nor dirty, nor has it a decidedly depressing influence on the patient, but, on the contrary, that it is a cleanly, rapid, and most manageable method, and the most powerful therapeutic agent in the removal of disease, and the least hurtful to the constitution of the patient. This latter will, of course, depend upon the care which is taken in watching the effect of the baths, and by properly timing the intervals between them. Even the administration of Mr. Lane's favourite blue pill would require similar precautions. This method of treating syphilis was employed by the late Mr. Langston Parker in thousands of cases, both in private practice and in the wards of the Queen's Hospital; and its astonishing effects were witnessed and appreciated by practitioners and students alike, and led to the deservedly great reputation which Mr. Parker enjoyed, not only in this country but on the Continent, and even in America, whence patients frequently came to place themselves under his care. Ninety-one fully reported cases are to be found in his book on *Syphilitic Diseases*. Many of these I had the pleasure of reporting for Mr. Parker; and I can most fearlessly affirm that they are a trustworthy record of the marvellous efficacy of this treatment, which was always open to the scrutiny of the profession.

As to what is thought of it in America, I would refer Mr. Lane to Gross's *System of Surgery*, vol. i, page 505, where he will find the following: "Another method of employing mercury is by a combination

of fumigation with steam, constituting what Mr. L. Parker of Birmingham terms the mercurial vapour-bath. I can testify from considerable experience to the beneficial effect of this method of mercurialisation, having effected some very extraordinary cures with it after all other modes of treatment had failed." And, again, "My opinion is that this method of treatment is not sufficiently appreciated; it certainly deserves the highest encomiums." Such is the opinion of this distinguished American surgeon, in contradistinction to that of Mr. Lane.

I will reply to Mr. Lane's allegations, by a short account of a case which has lately been under my care in the Queen's Hospital, and which is of such recent date that it will be in the recollection of many of our Birmingham readers.

E. O., aged 23, contracted a chancre about four years ago, for which he was treated by mercury, in the form of pills. Secondary symptoms soon appeared, taking the form of eruptions on the skin, and very severe sore throat. In due course, he suffered from an attack of rupia, the scars of which are plainly to be seen. He had also had syphilitic orchitis, which assumed such a form that his surgeon removed the affected testicle. He had taken mercury by the mouth in various forms, iodide of potassium, iron, and sarsaparilla. His medical adviser—one of the most able surgeons in this town—had given his case more than ordinary attention, as he took a deep interest in the young man. The treatment adopted appeared to relieve the symptoms for the time, with the exception of the ulcerations of the throat, which were never completely cured; but relapses took place as soon as the treatment was omitted. On coming under my care, he was in a most emaciated condition, and so weak that he ascended the hospital stairs with great difficulty. The uvula was completely destroyed, and there were deep excavated ulcers in the remnants of the tonsils; the pharynx was in a sloughing ulcerated condition, some of the ulcers being very deep. He could only swallow liquids with great difficulty; solids he had not been able to take for some time. The cervical glands were affected. His own impression was that he could not possibly recover. Up to the time of his admission into the Queen's Hospital, he had been taking mercury by the mouth in various forms, iodide of potassium, and opium; and he had had good and sufficient food as long as he could take it. I, at once, ordered him a nightly moist mercurial vapour-bath, containing hydrargyri bisulph., ʒij; hydrargyri oxidi cinerei ʒi; and a spray of black wash to the throat. He was directed to inhale the moist vapour while in the bath. A grain of opium was administered every night, to ease pain and procure sleep. The gums were touched after nine successive baths, and were kept spongy for nearly two months, the baths being given at varying intervals. The result of the treatment was, that the ulcers rapidly healed, and the patient gained twenty-eight pounds in weight in three months, notwithstanding "the depressing influence of the baths". He left the hospital looking fat and well, and feeling stronger and more vigorous than he had done since he had contracted the disease. The patient, who was a highly intelligent young man, watched the treatment with much interest, and I had some difficulty in restraining him from having too many baths, as he said they made him feel so comfortable and did him so much good. He has since remained quite free from a relapse, and has been doing twenty miles a day on the Devonshire moors.

This is no solitary case, but only one out of many which I hope, at no distant date, to lay before the profession in a more extended form.

CLINICAL RECORD OF CASES ILLUSTRATING THE TREATMENT OF ACUTE RHEUMATISM BY THE PACKING PROCESS.*

By THOMAS STRETCH DOWSE, M.D., F.R.C.P. Edin.,
Medical Superintendent Central London Sick Asylum.

CASE I. *Acute Rheumatism, with Pericarditis.*—S. G., aged 33, was seized, on February 27th, with general malaise, shivering, and headache. On February 28th, the symptoms and signs of acute rheumatism were well marked; every joint was swollen and painful. The breathing was oppressed and hurried. There was also pericarditis. Temperature, 101.4 deg. On March 1st, the patient was packed for six hours, and sweated profusely. She was allowed to drink freely of warm milk and water. The temperature during the pack rose to 103.6 deg. Pulse, 132; respirations, 30. The urine was acid, of specific gravity 1028. After being packed, she was quite free from pain. On March 2nd, she was packed for four hours. The pain in the joints had returned, but in a much milder form. The sweat still had the rheu-

* See BRITISH MEDICAL JOURNAL for January 9th, page 39.

matic odour. Frictional pericardial sounds were less marked. The temperature during the pack was 102.4 deg.; pulse, 126; respirations, 24. The urine was acid, 1028. After the pack, she was quite free from pain. On March 3rd, the patient was absolutely free from pain. She complained of stiffness in the limbs, but could move them in any direction. The pericardial murmur had quite disappeared as well as the acid odour of the sweat. Temperature, 100.4 deg.; pulse, 118; respirations, 24. On March 4th, she sat up in bed, and moved the limbs freely in any direction; she was quite free from pain. Temperature, 99.6 deg.; pulse, 109; respirations, 20. Urine acid, 1020. On March 6th, she was convalescent. The heart-sounds were quite normal. No medicine or stimulant was given in this case from first to last.

CASE II. Acute Rheumatism associated with Old-standing Mitral Disease.—R. C., aged 35, came under treatment on the fourth day of the attack with signs and symptoms well marked. On March 10th, packing was applied for six hours. The patient drank freely of warm milk and water with six ounces of brandy. The temperature before packing was 102 deg.; during packing, 104.4 deg.; pulse, 120; respirations, 28. On March 11th, the patient was almost completely free from pain, and complained mostly of stiffness in all the limbs. The dyspnoea, which on the previous day was at times urgent, had become less. The patient was packed for four hours. Four ounces of brandy were given, and warm milk and water. Temperature before packing, 101.2 deg.; during the pack, 102.8 deg.; pulse, 122; respirations, 28. On March 12th, the patient was much better in every way. All the joints were free from pain, except the right elbow and wrist. The pack was applied for two hours. Temperature before packing, 100.6 deg.; during the pack, 101.6 deg.; pulse, 112; respirations, 24. On March 13th, the patient could sit up in bed, and move the limbs freely in any direction. There was scarcely a trace of dyspnoea. The acid odour of the sweat had disappeared. The urine was acid and loaded with lithates. Tongue furred; temperature, 100.4 deg.; pulse, 98; respirations, 20. From this date, the pain did not return. Bark with ammonia was ordered; and the patient was convalescent in a week.

CASE III. Acute Rheumatism, with Endocarditis.—Nurse C., a young woman of dark complexion, not of typical rheumatic diathesis, was seized on April 24th with rigors, and, on the following day, presented all the signs and symptoms of acute rheumatism. The tongue was thickly furred, and, in the median dorsal line, was dry and of a mahogany colour. The joints of the lower limbs were acutely painful, and distended with fluid. On April 25th, she was packed for six hours. She drank freely of warm milk and water, with six ounces of brandy. Temperature before packing, 101.4 deg.; during the pack, 105.2 deg.; pulse, 110; respirations, 20. Thirty-six ounces of urine were voided in the twenty-four hours; it was acid, of specific gravity 1018. On April 26th, after the packing, the pain had subsided; but to-day there was a tendency to its return. She was packed for four hours. Four ounces of brandy were given. In the evening, the breathing was hurried, and the heart's first sound at the apex was obscured. Temperature before packing, 101.8 deg.; during the pack, 105.2 deg.; pulse, 110; respirations, 20. The urine voided in twenty-four hours was thirty-five ounces, of specific gravity 1017, acid. On April 27th, the patient was quite free from pain and from acid sweating. She was ordered to take five grains of blue-pill at bedtime, and a saline purge the following morning. She was packed for two hours. Two ounces of brandy were taken. Temperature before packing, 101.6 deg.; during the pack, 102.6 deg.; pulse, 122; respirations, 20. The urine voided in twenty-four hours amounted to fifty ounces, of specific gravity 1017, and acid. On April 28th, there was complete absence of pain. The heart-sounds were normal. She could move her limbs freely. Temperature, 100.2 deg.; pulse, 100; respirations, 30. Fifty-seven ounces of urine were passed in the twenty-four hours; it was of specific gravity 1026, and acid. On May 1st, she was convalescent. Temperature, 99.2 deg.; pulse, 70; respirations, 15. The urine passed in the twenty-four hours was sixty ounces, of specific gravity 1012, and acid. From May 1874 to the present date, the patient has been under constant observation. There has been no return of the rheumatism, and no cardiac mischief.

CASE IV. Acute Rheumatism complicated with Old-standing Valvular Murmurs and Recent Pericarditis.—E. R. was admitted with a fourth attack. The countenance was livid, and the breathing hurried. There was marked pericarditis, and a systolic murmur both at base and at apex. Almost every joint was swollen and painful. There was no orthopnoea. On June 11th, the patient was packed for six hours. She drank freely of warm milk and water, with six ounces of brandy. Temperature before the packing, 101.8 deg.; during the pack, 103.2 deg.; pulse, 120; respirations, 36. On June 12th, the patient was quite free from pain, except in the finger-joints and muscles of the

back. The pericardial murmur was less marked, and the profuse sweating had completely subsided. She was packed for four hours. Four ounces of brandy were given. Temperature before the pack, 100.6 deg.; during the pack, 101.4 deg. On June 13th, she was markedly improved. The pericardial friction-sound had quite disappeared. There was no effusion. She was packed for two hours. Three ounces of brandy were given. Temperature before the pack, 99.8 deg.; during the pack, 100.4 deg.; pulse, 96; respirations, 32. On June 14th, she was quite free from pain, and could sit up in bed and move the limbs freely in any direction. There was considerable hypertrophy, with dilatation of the heart. The apex reached the seventh rib. There was a systolic murmur heard over both the aortic and the mitral valves. The livid appearance of countenance and the dyspnoea had both disappeared. Temperature, 99.2 deg.; pulse, 84; respirations, 32. On June 15th, she was comparatively convalescent. It will be seen that the ratio of respiration to pulse was in excess of what it ought to be; but the breathing was not urgent or laboured. She was ordered a mixture of quinine, digitalis, and steel. Pulse, 76; respirations, 32. On June 16th, she was quite convalescent from the rheumatic attack. She was, however, weak, and moving hurriedly increased the action of the heart, and gave rise to dyspnoea.

CASE V. Acute Rheumatism complicated with Endocarditis, Mitral Systolic Murmur, and Basic Pneumonia.—W. C., aged 16, was seized with rigors on May 16th, and came under my care on May 22nd. There was acute pain in every joint, with general myalgia. Pneumonic crepitation was heard at the bases of both lungs posteriorly. The breathing was dry and harsh, with coarse crepitant rhonchus. There was distinct pleuritic rubbing over the left lung anteriorly (lower lobe). There was a confused intraventricular murmur, as well as a fine systolic whiff, at the heart's apex. On May 22nd, the patient was packed for six hours. He drank freely of warm milk and water, with three ounces of brandy. Temperature before the pack, 102.2 deg.; during the pack, 104.2 deg. Pulse, 140; respirations, 40. On May 23rd, he was quite free from pain. The dyspnoea continued urgent. He complained of feeling stiff all over. Sour sweating still continued. He was packed for four hours, and drank three ounces of brandy, with warm milk and water. Temperature before packing, 101.8 deg.; during the pack, 103.6 deg. Pulse, 132; respirations, 40. On May 24th, he had markedly improved. The anxious expression of countenance was quite gone; and there was much less dyspnoea. A clear mitral systolic murmur was heard at the apex of the heart. He could move his limbs freely in any direction. He was packed for the third time for two hours. Two ounces of brandy were given with warm milk and water. Temperature before packing, 100.6 deg.; during the pack, 102.4 deg. Pulse, 120; respirations, 32. May 25th.—Pulse, 100; respirations, 32. On May 26th, the rheumatic poison was quite eliminated. Temperature, 100; pulse, 94; respirations, 28. On May 27th, he was nearly convalescent. He was ordered to have three ounces of brandy daily, in order to lessen the formation of urea. Temperature, 99.2 deg.; pulse, 100; respirations, 22. On May 28th, he was convalescent. The temperature, respirations, and pulse were normal. This patient has been constantly under my observation until the present time. The mitral systolic murmur is still persistent.

CASE VI.—Acute Rheumatism: no Complications.—J. R. was admitted with all the signs and symptoms of acute rheumatism. Every joint was acutely painful, and on this account she was unable to move a limb. There was an endocardial murmur, not confined to any especial set of valves. Respiration was dry, harsh, and hurried. On May 18th, she was packed for six hours, and drank freely of warm milk and water. No stimulant was given. Temperature before packing, 101.6 deg.; during the pack, 103.4 deg. Pulse, 118. On May 19th, she passed a comfortable night; but had flying pains about the joints. The sour rheumatic smell was very marked. She was packed for four hours. No stimulant was given. Temperature before the pack, 100.8 deg.; during the pack, 102.2 deg. Pulse, 120. On May 20th, she was improving. Although the freedom from pain was absolute, yet the other symptoms of the rheumatic state were well marked. The tongue was furred; the urine scanty, high-coloured, and loaded with lithate. She was packed for two hours. Four ounces of brandy were given. Temperature, 100.4 deg.; pulse, 116. On May 21st, the brandy, with the packing of the previous day, had had a good effect. The patient was cheerful; could sit up in bed, and move her limbs with freedom. The urine was more copious. There was no profuse sweating or sour smell. Temperature, 99.4 deg.; pulse, 100. On May 23rd, the rheumatic poison had been completely eliminated. The respirations and heart-sounds were normal. No other medicine was given in this case than a saline purge. Temperature, 98.2 deg.; pulse, 78.

These are six fair average cases from among many (at least thirty) which I have submitted to the packing method: and, with the

exception of one case, none failed of success. I hope the treatment may be tried at the various hospitals, as I feel sure that the statements contained in my paper will thus be verified. I can well remember the time when acute rheumatism was said to be of six weeks' duration under any treatment. And it comes to be a question whether the type of this disease has not altered within the last twenty years. Of this I am certain: that the constitution or age of the patient does not so much influence the duration of the disease, as the season of the year and state of the atmosphere. I have repeatedly observed that, if a patient with acute rheumatism in one ward have a relapse, it invariably follows that patients in other wards are similarly influenced.

To carry out the treatment without failure, the prescribed regulations must be strictly adhered to. For instance, to pack a patient at first for two or three hours has been found, in my experience, to be worse than useless. Revulsion must be started; the skin must be made to act freely, and the temperature must be raised. When this is done, the inhibition of the vaso-motor centres will be relieved, the impeded action of the secretory glands will be removed, malassimilation will be remedied, and morbid material will be eliminated. My treatment is, in fact, a mode of assisting nature.

REMARKS ON TROPICAL FEVERS.

By W. T. BLACK, F.R.C.S.E., Surgeon-Major, Edinburgh.

WHEN stationed at Hong-Kong, a few years ago, I witnessed an epidemic of tropical fever, accompanied with cholera, dysentery, and hepatitis; there was a great sickness and mortality amongst the troops there in consequence.

Enlarged spleens were found common in nearly all fatal cases of intermittent fever, sun-stroke, and other diseases; and enlargement of the liver was nearly as frequent, especially in remittent fevers and dysentery. These two organs seemed, therefore, to act as banks in the body, in which were stored up deposits of malaria and miasmata, which increased till the accumulation seemed, as it were, to reach an explosive tension. Then some exciting cause permitted the stored up poison to inundate the system, producing fever probably from the efflux from the spleen, and dysentery from that of the liver.

The remains left in the organs, after a recovery from an attack of fever, may probably make another attempt to break forth into the system, when a relapse of fever would be likely to be the result. Hence it might be conjectured that relapses would be liable to recur, till the spleen and liver had finally got rid of all their malarial and miasmatic contents.

It may be considered very likely that the infection of tropical fevers may be conveyed into the system, as much by the stomach imbibing bad water, as by the lungs inhaling bad air. This may be inferred from the much greater frequency of affections of the liver and spleen, than of the lungs and heart, and their consequent reactionary effect on the large and small intestines.

Regarding the medical treatment at the time of invasion, quinine seemed to be of more value in intermittent fevers than in remittent, where calomel and arsenic proved of better use.

In the after constitutional treatment, at home, of invalids from tropical countries, I am inclined to recommend a course of the warm mineral baths of Bath, where there is first-class accommodation and appliances, both for the wealthy as well as for the lower classes. I am much surprised that the excellent Mineral Water Hospital there has not been utilised more for the benefit of soldiers, marines, and sailors, who have suffered from the sequelae of diseases contracted in tropical climates. These waters, from their containing iron, do not debilitate, but rather strengthen the skin, when used for warm bathing; and the gases which they contain in combination render them, with their warmth, light and exhilarating to drink.

The German Government have established at Wiesbaden a fine mineral-water-hospital for the use of the invalids of the Imperial Army, free for private soldiers, and officers paying their messing, which I have had the privilege of visiting; and it appeared to be furnished in the best of modern comfort, and to be fitted up with the newest appliances for treatment.

The physical causes of tropical fevers continue to exist as effective as formerly at Hong-Kong; for, if the marshes be drained, the mud still remains to evolve malaria when called upon, and, in addition, there is an immense increase in the deposit of sewage on the hill-sides from the increase of the Chinese population, to generate miasmata.

The debatable question concerning the origin of morbid vapours from the *latrines*, exposed in excavating for the foundations of new houses, admits of explanation, from its being so porous that it is something like

a mineral bog, which exhales, under exposure to a tropical sun, all the mephitic moisture it had already absorbed.

In regard to the chilly doctrine of Drs. Oldham and Inman, it may be remarked, that the daily range of temperature is far greater at the Cape of Good Hope, where fevers are absent, and cold nights are common, than at Hong Kong, where fevers are endemic, and sleep is nearly impossible from the heated air, in the summer months. The contrast of the climates of these two places, at that season, is remarkable; the ozoniferous south-east winds, in the summer, at the Cape, blow from the circumpolar latitudes dry and cool, whereas the south-west monsoons at Hong-Kong breathe hot and moist from the simmering China seas, laden with the distilled vapours from the coast lagoons.

A CASE OF PAROXYSMAL FEVER CAUSED BY DISTURBANCE OF THE SOIL:

WITH SOME OBSERVATIONS IN REPLY TO DR. INMAN.

By P. DIVORTY, M.B., L.R.C.P. Edin., Inverurie, Aberdeenshire, Late 11th Regiment, and Honorary Physician to the Carlisle Dispensary, etc.

IN submitting the following case, I do not propose to "stand forward"—to use an expression of Dr. Inman's—in behalf of Dr. Maclean, as that gentleman has already shown that he is quite able to defend himself; but simply to furnish a case of malarious fever of which the soil, and nothing but the soil, could have been the cause.

I may state at once that, in this case, I was not only an observer, but a sufferer; and that, unlike Dr. Inman, I have had considerable experience of malarious fevers in Hong Kong and elsewhere, although, fortunately for myself, I had escaped an attack of it until the autumn of 1872. In October of that year, I took on lease a newly-built house in Portland Square, Carlisle, where the soil had recently been disturbed, not only for building purposes, but also for making a new street along the front of the house, as well as a road and small garden at the back. I accordingly sent a maid to keep fires constantly burning in every apartment till the house was thoroughly dried; and, inasmuch as the house was one of the best in Carlisle—having been constructed under the personal supervision of an architect of at least local eminence, with all the sanitary arrangements complete—I could not have anticipated an untoward result on my taking possession in November. On the first night of my sleeping in the house, I was struck down by a severe attack of paroxysmal fever; though, properly speaking, I was not living in a malarious district, had in no way been overheated by violent exercise or otherwise, nor had been in any way chilled. The fever, which lasted nine weeks, was marked by the shortness of the cold stage, the length of the hot, and the number of paroxysms occurring in one day, as well as by the singular circumstance of the strict limitation of the malarial influence to the house and so many yards around it. So well defined was the limit of its operation, that I could at any time stop a paroxysm by going a certain distance from the house; and invariably did I feel its influence on returning within the tainted area, as a paroxysm supervened the instant I entered the house, which appeared to be the very focus of the malarial atmosphere around, from the air outside being sucked into the warm house.

My prolonged suffering was no doubt owing, in part at least, to the failure of quinine from irritability of the stomach and vomiting; but the disease yielded eventually to the administration of liquor potasse arsenitis combined with morphia.

Such, then, having been the circumstances under which I suffered so intensely, it is incomprehensible to me how either the "chill theory" of Dr. Oldham, the "electrical conditions" of Dr. Munro, or the "hot days and cold nights" of the Indian colonel, or any combination of them, could, by any amount of straining, be made to grasp the train of symptoms I have enumerated; and therefore I ask a second time the question which caused so much merriment to Dr. Inman—the question, namely, If the soil in the above case did not cause the disease, what did?

The first thing that will naturally strike anyone who looks carefully over Dr. Inman's communication to the BRITISH MEDICAL JOURNAL of January 2nd, will be the meagre amount of proof, if any, which he brings forward in support of the "chill theory" of Dr. Oldham; for it will be seen that his contention is: 1. That, because Dr. Oldham tested the malarious theory by sleeping on a bed placed in a marsh, and did not get the fever in that way, but by getting chilled in a room cooled by a punkah; 2. That, because only those suffer from disturbance of the soil who work hard at digging it up under a hot sun, and who get chilled by the cold at night; 3. That, because an Indian colonel

told Dr. Oldham that hot days and cold nights were certain to produce fevers: therefore there is no such poison as malaria. Now, I hold that these are merely assertions without proof: because, in the first place, I deny that Dr. Oldham did test the malarious theory in any legitimate sense of the word by sleeping so many nights on a bed placed in a marsh; for I maintain that his escape from an attack of fever under the circumstances is no more a proof of the non-existence of malaria, than the escape of an individual from an attack of sea-sickness, who may have slept on board a ship in the Bay of Biscay for two months during a storm, is a proof that the motion of a vessel is not the cause of such sickness. In the second place, I deny that only those who work hard in turning up the soil under a hot sun suffer: because, as has been seen, my own case is a notorious instance to the contrary. In the third place, I deny the assertion that "hot days and cold nights" are *per se* the cause of malarious fevers, because my own case entirely disproves it. When Dr. Inman, who, at the commencement of his paper, postulates the non-existence of malaria, makes use of such expressions as "in malarious districts the temperature of those working in the sun", and "every notoriously malarious district is marshy", it is not only a case of confusion, but it is a contradiction in terms.

CHILL AND MALARIA.

By W. J. EAMES, L.K.Q.C.P., Staff-Surgeon R.N.,
Royal Hospital, Haslar.

THE question at issue between Drs. Maclean and Inman cannot but create feelings of surprise in the mind of anyone who has had to deal practically with paludal fevers; surprise, not only that the existence of a specific factor—call it by what name you will—has been called in question, but that the gentleman to deny its existence should be a teacher of medicine, who, it may be assumed, has been in the habit of inculcating such doctrines amongst his pupils. However, after the views that have been expressed by one or two members of the profession with reference to the non-existence of a specific virus in such diseases as syphilis and gonorrhœa, we may well cease to feel surprise at anything. As regards the two latter diseases, any individual who is sceptical on the point can probably demonstrate the fallacy for himself: but he cannot expect commiseration, should he have the misfortune to find out that he has been labouring under a mistake.

The case, however, is far different when the belief in, or denial of, the existence of such a poison as malaria is the question to be determined. The health of a ship's company or a regiment is placed in the hands of one man, and the lives of hundreds may be sacrificed to a theory. It is for this reason that I think it incumbent on those who can speak from experience to cast the weight of that experience into the balance of truth, and, in the interest of humanity, to state what facts bearing on the question have come under their own observation.

In the first place, Dr. Inman, although he professes to despise the opinion of those who see for themselves, would, if his ideas were based on personal observation, never have fallen into the mistake he makes in his communication, namely, that "the folks attacked are not those who sleep between decks, but those who sleep in the open air". The history of the outbreaks of fever on board H.M.S. *Eclair*, *Archer*, *Icarus*, and *Bloodhound*, sufficiently refute such a statement. Moreover, he would have learned that there is not a ship in Her Majesty's service where, in tropical climates, awnings are not spread, and the greatest precautions taken to prevent men from exposing themselves at night without a covering. I would, therefore, ask him to account for the following outbreak of disease, according to his theory. In 1861, a cruiser on the West Coast of Africa, whose crew of white men numbered fifty-five, was taken from her cruising ground in the bight of Benin and ordered up the Niger. At this time, the ship's company were in perfect health, having never approached closer to the land than from three to seven miles for a period of three months. The ship remained three months in the river, and while beyond the Mangrove belt was comparatively healthy; unfortunately, on her return voyage, she was detained for a week amongst the swamps in the delta. Ten days had not elapsed after her return to the open sea before thirty-five out of the fifty-five were attacked with a severe form of what is popularly known as "coast fever"; and, out of the whole ship's company, only two entirely escaped. This, I may observe, was not a solitary instance; during three consecutive years, the same duty was performed by this ship with similar results, though in the last two trips the disease did not assume such extensive proportions. I will give another proof of the fallacy of attributing the deadly diseases of Africa to such causes as exposure to the open air at night, *minus* malaria. In all the African rivers where the palm-oil trade is carried on, it was the fashion

some years ago for a ship on her arrival to send down everything from aloft, and *house-in* by building a shed of palm leaves over the upper-deck. Here she remained till her cargo was completed, which generally required from three to four months; the men were not exposed, as the custom is to employ Kroomen for all work requiring exposure to the sun. It was found, however, that, by the time the ship was ready to start, the men were nearly all dead: consequently, she could not leave till a fresh crew could be got out. I do not mean to say that this was invariably the case; but it occurred so frequently that a different course of proceeding was adopted; and a ship now, on her arrival, transfers her crew to the one prepared to start. By this means, the loss of life is diminished 90 per cent. As to the prevalence of fevers of the paroxysmal type in the vicinity of masses of disintegrating granite, explain it how we may, it is a well known and admitted fact, not confined to Hong-Kong alone, but present wherever the necessary conditions of heat and moisture are found; in the tropics, Dr. Inman may depend that the means to be taken to insure immunity from these diseases has occupied the attention of men well qualified by previous training to avail themselves not only of the researches of others, but of what has come under their own observation. I cannot see that a "physician in his study" is, therefore, better constituted in any way to form an opinion on these matters than the "surgeon of a regiment", but, in my opinion, rather the reverse.

CLINICAL MEMORANDA.

NEW FORM OF CATHETER.

IN cases where it is necessary to tie in an ordinary gum-elastic catheter, I have frequently found that it has collapsed from pressure, after having become softened by the heat of the body, and has thus frustrated the object for which it was used; viz., the institution of a free outlet for the urine. To obviate this difficulty, I have devised the following. A spiral of fine wire is made, of similar construction to that used for lining flexible gas-tubing. Over the spiral a gum-elastic coating is put, with the ordinary perforations at the extremity. I find this instrument most useful, and much more durable than the ordinary form, the cost being but very little extra. Messrs. Lynch and Co., of Aldersgate Street, are the makers.

S. W. MOORE, L.R.C.P.Ed.

POISONOUS FUNGI.

IN reply to Dr. Hutchinson's interesting case of supposed poisoning by the edible mushroom, I can scarcely realise that the facts stated warrant the conclusion which he draws. His case had none of the usual and early gastric, or even narcotic, symptoms of fungoid poisoning, such as were shown in Mr. Sedgwick's and Dr. Drummond's cases (JOURNAL, pages 464 and 524, October 10th and 24th), due allowance of course being made for the symptoms varying in different individuals. There were also no tetanic spasms, although there certainly was cerebral excitement after several days had elapsed; but this could not have been caused by muscarine, because the action of the latter on the heart is speedy, which has been clearly proved by Dr. Lauder Brunton (page 617). The patient was in a condition of exhaustion previously, and his system was consequently ready at any time to receive any morbid impression; he partook, as is admitted, of a large quantity of fungi late at night. Surely a heavy meal under such circumstances may have produced cutaneous rash and meningeal irritation, from sympathy with the stomach. Does not the prudent huntsman, when greatly exhausted, first partake of some light stimulating food before he ventures on a rump-steak, and give his horse gruel before a heavy feed of beans? The sister appears not to have been affected, she being more prudent and taking less. If the fungi were of the esculent variety, they would rather tend to show that the effects were due more to a state of idiosyncrasy of constitution rather than to muscarine poisoning. Since the patient survived between two and three weeks, muscarine poisoning could scarcely have been the cause, as in that time the poisonous alkaloid muscarine, if present, would have exhausted itself. Again: if atropia be the true antidote to muscarine, why the increased excitement and the consequent abandonment of the remedy? Dr. Lauder Brunton has shown that "dyspnoea, as well as the other symptoms of muscarine poisoning, disappear in animals almost immediately after the injection of atropia"; and he quotes an instance where this "antidote during the death-struggle completely restored a dog which had been so poisoned". Under the circumstances, I cannot admit that the true mushroom—*Agaricus campestris*—in a healthy condition, and properly cooked, could have acted as a poison in the ordinary acceptation

of the world; but, from idiosyncrasy, it might have acted as an irritant, as I stated in my article on Fungoid Poisoning (JOURNAL, November 21st, page 645). This question is not only important to the profession, but to the public generally, and should be freely ventilated, in order to show whether, under circumstances unfavourable, the mushroom can act as a specific poison, or simply as an irritant.

ROBERT CUFFE, M.R.C.S. Eng., Woodhall Spa Villa.

MALARIA V. CHILL.

THE importance of the verdict the profession will give in the above cause must be my apology for proffering some suggestions and evidence. The first is, that Dr. Maclean has overlooked the point that might be deduced in favour of his argument in the result of fen drainage, referring especially to Norfolk and Lincolnshire. Thirty or forty years ago, the surface of these fens was covered with stagnant water and rank vegetation; the residents in their vicinity suffered from intermittent fever, whole families at a time were stricken with it, and most of the labourers employed on them suffered an annual attack. Drainage removed water, and cultivation rank and decaying vegetation. There is no evidence to show that the temperature of the air of the locality was changed by either process, or that the residents became less liable to chill; but the statement that, since then, they have not been subject to fever is incontrovertible. The counsel for "chill" aduces Aden as evidence of fever infesting a place where malaria must be absent—absent because its factors, moisture and vegetation, are; and he implies that fever, not being produced by malaria, must be by chill. The evidence by which he supports this theory can be much shaken, inasmuch as the factor of chill is as conspicuous by its absence as those of its opponents are. Aden is very hot (this sentence is so inadequate to convey my meaning, that I might almost as well write, it is very cold). The climate is extraordinarily equable, and the night is hotter than the day, because the sea-breeze fails at sun-set—in no part of the world would one be less liable to chill. Supposing malaria to exist, there is no reason for supposing it to be strictly localised, that it cannot be conveyed by the atmosphere. Within twenty-five miles of Aden, at a place called Zaida, in Arabia, intermittent fever is a plague that has depopulated the country; no one but the African Seedi can live in it. In 1872, the Aden troop was sent there (natives of Seind and Bombay), and scarcely a man escaped fever. In 1873, a portion of the 105th Light Infantry went, remained there for some three or four days, and returned to Aden. On their return, there was little or no sickness amongst them, but within sixteen days there was scarcely a man who had not intermittent fever. I say scarcely one; one did escape, an officer, who took quinine as a prophylactic; the others continued to suffer at intervals until their arrival in England months afterwards. In all these cases, one symptom was ever present, that pointing to congestion of the liver, and there was always mental derangement of it. The malarial could, of course, be produced by chill, but then the effect would at once follow the cause; in the cases referred to, there was a distinct period of incubation, varying from four to sixteen days.

Instinct seems to teach the natives of India self-preservation; at night-time, in Bengal, camp followers may be seen, even in the rainy season, laid out in rows to sleep on the sodden ground, with no clothing but a cloth of cotton, and that tightly drawn over the head and face. How they breathe is a marvel to white men; that this cloth can save them from chill is improbable; but it is possible that the air, in filtering through it, is robbed of its poisonous element, as is that filtered through carbolised muslin.

That malaria in the unit or aggregate has not been demonstrated, is not wonderful, when we consider that several years ago bacteria were unknown, we now know how potent for evil they are, and that their length is only 1-9000th of an inch.

W. HAWARD, Surgeon-Major late 105th Regt., Bury, Lancashire.

OBSTETRIC MEMORANDA.

RETROVERSION OF THE GRAVID UTERUS: RETENTION OF URINE: RECOVERY.

IN response to the request of Dr. Edis for a record of these cases, I send the following.

H. R., married, mother of six children, rather small in stature, thin, but active and wiry, had had difficulty in passing her urine, and had been gradually becoming worse for a week, until, at the time when I was sent for, she could not pass any, or only a few drops at a time. She stated that she was about three months pregnant, and could not explain the difficulty in passing urine by any special cause. When

seen, her countenance was dusky and haggard; the cheeks flushed; the tongue dry, striped, feverish; pulse quick, small, thready. She complained of much pain in the lower abdomen, which latter was distended and dull on percussion. The catheter passed with some difficulty perpendicularly upwards and forwards behind the pubes, and an immense quantity of turbid, high-coloured, strong-smelling urine was drawn off. The uterus was retroflected; the os was high up behind the pubes, and could not be found. On examining *per rectum*, the fundus uteri was detected filling up the hollow of the sacrum. The prone position was enjoined; but the inability to pass urine returned, and the catheter was again employed the following day, when the whole hand was passed into the vagina, and efforts made to replace the uterus, but ineffectually. After trying catheterism and the prone position for a day or two without success, the patient was placed in the knee-shoulder position, Dr. Davis assisting; and, with the fingers of one hand in the rectum and of the other in the vagina, the fundus was pressed forwards and replaced with a distinct "flop". The prone position was enjoined, and no further use of the catheter was required. The urine recovered its healthy character, and the patient went her full time.

In a midwifery experience of over three thousand cases, this is the only confirmed case of the kind I have ever had, though I have met with other cases necessitating the use of the catheter, where the calls to empty the bladder have not been attended to. Partial retroversion may have been present, but did not require manual interference for reposition.

WILLIAM BROWN, M.R.C.S. Eng., Callington.

REPORTS AND ANALYSES AND DESCRIPTIONS OF NEW INVENTIONS IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

A NEW BELT.

MESSRS. SALMON, ODY AND CO. have submitted for inspection a lady's and a gentleman's belt, which they are now making according to Dixon's patent. The novelty consists in the use of strips or layers of cork, instead of steel or whalebone. The cork is rendered unbreakable by being stitched between two substances. They are light, serviceable, and the substitution of cork for metal appears to be a decided advantage.

POLYPUS KNIFE-HOOK.

By W. LAIDLAW FURVES, M.D.

As the methods of extracting aural polypi, numerous though they be, do not always lead to satisfactorily speedy results, on account of the breaking of the polypus, the difficulty of adjustment of the snare, and the narrow room to work in with scissors, forceps, guillotine, or other like cutting instruments, I have proposed the use of a probe-pointed hook, with a sharp cutting edge on the concavity, for the purpose of removing soft growths from the external meatus. Mounted on a metal handle sufficiently small to pass through any ordinary speculum, with curves of different sizes to suit different meat, it is more easy of adjustment than a wire snare; and, being single-limbed, does not take up the room that a double-armed instrument does. It has the advantages that both snare and forceps possess, in that, like the former, it does not drag upon any parts with which the polypus may be connected, and, like the latter, it is easy of adjustment, and requires little or no practice to use it.

MACKAY'S OMPHALIC MUSTARD PLASTERS.

WHATEVER opinion may be entertained in regard to the *modus operandi* of counterirritants, their usefulness is beyond question. Mustard is perhaps more commonly employed than any other. Not only is it usually at hand, but it is exceedingly efficacious. The common mustard poultice, however, is clumsy, and attended with much that is disagreeable. Specimens of counterirritant plasters ready-made in both mustard and cantharides on a new principle, have come under our notice.

Mackay's omphalic mustard plasters or leaflets consist of discs about the size of a sixpence, attached to small sheets of a light and transparent material. These are four and a half inches by three and a half, and have each twenty spots. They have merely to be dipped in water and applied. By leaving them on for a longer or shorter time, any required amount of effect may be attained, from a glow of

redness to actual blistering. It appears to us that this kind of plaster will prove very valuable to the profession, as by means of it a slight or a powerful effect may be readily produced. The spot principle, too, seems quite in accordance with Nature's own efforts to relieve internal congestion and inflammation, as in the various rashes which from time to time appear on the body. It is well known that the appearance of such is attended with much relief from suffering. The same principle has been applied to fly-blisters. With phlebotomy and cupping, fly-blisters have of late years fallen very much into disuse. The old-fashioned fly-bliſter spread on leather is a most forbidding-looking and smelling thing. It is attended, too, with most painful and disagreeable effects. It is apt to slip and blister in a wrong place, and the flies often fall off and vesicate on other parts of the body. Mackay's omphalic fly-blisters are much superior to anything in this way which has yet appeared. The spots are of three sizes, but those most recommended are small—four-tenths of an inch—and eighty-five of them on a sheet six inches square. They occasion a crop of vesicles, which appear in regular order, having intervals of unblistered skin between. This rash of small blisters, as they appear to one for the first time, is something quite striking. What renders common blisters so painful, is the denudation of a large continuous surface of the sensitive skin. The spot plan entirely does away with this, leaving as it does sound intervals between the vesicles, and making it an easy matter to heal them up when this is wished for. By removing the cuticle and applying a drawing ointment, the counterirritant effect is kept up, and may be intensified as much as may be deemed desirable. We think it likely that omphalic fly-blisters will supersede not only the common cantharides blistic, but blistering liquids and tissues of all kinds, and will be employed in cases in which the ordinary fly-bliſter would never be thought of.

COLUMN FOR THE CURIOUS.

THE EARLY HISTORY OF SYPHILIS.—As the early history of syphilis has been a subject of great interest and research for some time past, it has occurred to me that possibly an allusion is made to this disease by King David in the 38th Psalm, about one thousand and twenty years before the Christian era. Whatever he may have suffered, from the description he gives (be it poetical, allegorical, or otherwise) of his trouble, it cannot but remind one of syphilis in an advanced stage in the present day; and more especially if this be read in conjunction with the account given by King Solomon, in the 7th chapter of Proverbs, of the then existing state of "the social evil", which is strictly applicable to the state of things in the nineteenth century.—F. D. Z.

LYCANTHROPIA.—Oribasius, who flourished about the year 380 at Constantinople, gives the following description of the disease called lycanthropy, evidently that under which the demoniacs laboured whose miraculous case is related by the first three Evangelists. "The persons affected go out of their houses in the night-time, and in everything imitate wolves, and wander among the sepulchres of the dead until daybreak. You may know them by these symptoms: their looks are pale; their eyes heavy, hollow, dry, without the least moisture of a tear; their tongue exceedingly parched and dry; no spittle in the mouth; extreme thirst; their legs, from the falls and bruises they receive, full of incurable sores and ulcers."

A LITERARY CURIOSITY.—An extraordinary example of the close alliance which formerly existed between ophthalmology and charlatanism, is to be found in a rare little pamphlet, entitled, *A Parallel between the late celebrated Mr. Pope and Dr. Taylor, Oculist to the King of Great Britain, &c.* By a Physician, 1748. The Dr. Taylor referred to was the famous Chevalier Taylor, and the parallel in reality only an impudent and extravagant puffing of this worthy. A diploma was granted to him by the University of Basle, and the following extract from it serves to contribute towards the parallel. It forms an astonishing contrast to the modest testimony offered on the bits of paper or parchment of the present day. It says, "In the knowledge of the nature and cure of the diseases of the eye, Doct. John Taylor has, in our judgement, greatly surpassed all others; and tho' yet very young (which seems almost incredible!) he has not only left very far behind him in his skill in this science, all who ever lived before him, but even all those of his own times. He has made known to the whole universe, to the great astonishment of everybody, not by vain ostentation (?) but by experiments daily made; that he has a genius formed by nature for this sort of study, an industry surprising, an application inconceivable, and, above all, in the practice and address and delicacy nowhere to be equalled; so that we may justly say, that heaven, out of

a particular favour to our age and posterity, has given birth to him only in these our days, to cultivate and bring to perfection this noble and useful study". For a contrast between the sham and the true chevalier, we must compare with the foregoing the following extracts from Horace Walpole's letters (Cunningham). In a letter to Sir Horace Mann, he says, "I need not desire you not to believe the stories of such a mountebank as Taylor. I only wonder that he should think the names of our family a recommendation to him at Rome; we are not conscious of such merit; nor have any of our eyes ever wanted to be put out". And in another letter to the same is the following witty epigram, written when the claims of the House of Stuart to the British throne were still urged.

"Why Taylor the Quack calls himself Chevalier

'Tis not easy the reason to render,

Unless blinding eyes that he thinks to make clear

Demonstrates he's but a Pretend'r."

A son and grandson of the chevalier were successively oculists to royalty, and the grandson was a man of some literary merit, and the author of *Monsieur Tenison*.—LLOYD OWEN, Birmingham.

SELECTIONS FROM JOURNALS.

MIDWIFERY.

CESAREAN SECTION.—Dr. J. Cerf-Mayer, Surgeon in the French Navy (*Archives de Médecine Navale*, November 1874) details from his practice at Brest a successful case of Cesarean operation. E. L., aged 30, a primipara, married fifteen months, had arrived at her full period. She was deformed from rickets. Spinal curvature was great. The pelvis measured $1\frac{3}{4}$ inches. She was bow-legged. A median incision 7 inches long was made from 1.2 inches below the umbilicus to 0.6 inch above the pubes. The uterus then presented, of violet hue. The amniotic fluid had been evacuated through the os previous to the first incision, and none escaped through the incision into the uterus. Every drop of blood was sponged away. The membranes being opened, a male child weighing seven pounds was extracted, and the placenta was removed by enucleation with the forefinger. A little effused blood was removed by means of sponges, and cold water was used as a styptic. A drainage-tube of a finger's breadth on a few loops was passed through the vagina and uterus, brought out at the incision, and fixed on the pubes, so as to facilitate the subsequent escape of pus or lochial discharges. No sutures were applied to the uterus itself, and six of silver wire were lightly drawn to close the external incision. The operation was performed under chloroform in a spacious apartment facing the south, and was completed in twenty-five minutes. The dressings were a fenestrated piece of cerated lint, covered with cold-water pledgets, and a lightly applied bandage. No hamorrhage followed, and micturition was not affected. On the sixth day, the drainage-tube was removed, and injections of carbolic acid in aromatic decoctions were begun for the cleaning of the vagina and uterus, and ricinated collodion was applied frequently over the abdomen the next six or eight days, to diminish the intestinal inflation. No symptoms of metria, of metropéritonitis, or of hamorrhage, supervened. From the twelfth to the fifteenth day, she was able to take a few steps across her room; and on the thirtieth day she went out with her infant. The complications were as follows. On the sixth day, a large protrusion of hæmorrhoids was treated by suppositories of belladonna in cocoa-butter. On the sixteenth day, diarrhoea appeared; and, during the following three days, there were symptoms of enteritis. Under the use of poppy fomentations, laudanum, and bismuth, diarrhoea had ceased on the twenty-first day, when phlegmasia dolens attacked the left leg. This was treated with emollients, cotton-wadding, mercurial unction, and belladonna. The general treatment was, after the operation, thirty grains of ergot; and at night, forty-five grains of chloral hydrate, which was rejected. On the third day, a lavement of castor-oil brought away much flatus and very black solid feces, after which the abdomen became supple. From the first day up to the seventh day, sulphate of quinine was administered daily in doses of twelve grains, and, after the seventh day, in decreasing doses through the next fifteen days. The diet was at first of cold soups, with draughts of warm claret; and, in a later stage, nourishing and tonic food. Dr. Cerf-Mayer lays great stress on the advantage of spacious sanitary accommodation in all the capital operations, and on the steady administration of quinine. As to the mode of operating, he thinks that each case and every operator may require variations; but he doubts that the success will be much influenced by these, and believes that much more depends on the personal attentions of the operator during the operation and throughout the subsequent treatment of the patient.

BRITISH MEDICAL ASSOCIATION: SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, JANUARY 23RD, 1875.

MR. STANSFELD'S SANITARY SYSTEM.

PERHAPS the most interesting portion of Mr. Stansfeld's address at Halifax, some of the more salient points in which were briefly discussed in this JOURNAL last week, was that in which he explained the principles that had guided the Local Government Board in initiating the Public Health Act, 1872. Our readers well remember how that imperfect piece of legislation was made needlessly futile as to its ultimate objects by the unskilful manner in which it was put in operation. We now learn that this presumed unskilfulness was the result of acute political insight and profound sanitary pedagogism. Ignorance as well as knowledge, according to the Local Government Board (so at least we gather from Mr. Stansfeld) has its claims in the commonwealth; and, in respect to sanitary administration and organisation, ignorance has the first claim to consideration. It is no part of our purpose to question the paradox. We propose simply to show how it has been acted upon as a State precept. If it suggest, as a parallel argument, Dean Swift's thesis on the uses of lunacy in a commonwealth, we must beg of our readers to discard such seeming resemblance: for the one was a keen satire, the other is an administrative fact.

Mr. Stansfeld states that the first great step of the Local Government Board on firm ground in sanitary work was to organise local authorities, and to impose positive sanitary obligations on them by law. This was effected. "The whole philosophy of the subject", he continues, "was contained in the answer to this question, What was, or ought to be, the next step? The next step, in the opinion of the Board, was to be an educational step. The sanitary law had to be administered by local representatives; it could only be efficiently administered by securing their intelligent co-operation by enlisting them, of their own free will, in the work." The Board, therefore, began its pedagogic duties by assuring local sanitary authorities (after the manner to new scholars of the old-fashioned dominies, the very remembrance of whom revives the smart of their fundamental encouragement of instruction) that "they had no design of putting force upon them". The cane was there, suspended in the legislative rack, but the Board announced its intentions of educating through the intelligence, not the breech. In reality, it proposed to leave sanitary authorities to their own unaided self-instructive devices, except in those cases where they received pecuniary aid for local services, when the Board "claimed the right to take common counsel with them, and in that common counsel to seek to persuade them towards its own views".

Now, the first matters in which the Board was called upon to educate local authorities were the appointments of inspectors of nuisances and of medical officers of health. It has been generally believed that the appointment of these officers was designed primarily for the execution of certain prescribed duties, and this belief has been fostered by sundry regulations issued by the Local Government Board on the subject. This, it would now appear, is an error, and to this error is owing much of the misapprehension of the action of the Local Government Board as to these appointments. Mr. Stansfeld tells us that the view of the Board was, that "inspectors of nuisances should be appointed for areas which would occupy the whole time of a competent man, and which would make it possible to pay him sufficiently well to secure a

fair chance of honesty and independence in the performance of his duties; and, secondly, that precisely the same principle should be applied to what ought to be the *higher* (!) appointments of medical officers of health". In other words, that the question of salary should regulate the area of the district of an inspector of nuisances and of a medical officer of health, not the nature of the duties to be performed. Such satisfaction as Mr. Stansfeld expresses in some successes of this policy must be interpreted, therefore, merely with reference to the areas and salaries secured, not with reference to the practicability or not of the performance of the duties for which the salaries are given and the areas defined. "The first idea" of professed and scientific sanitarians is "health", Mr. Stansfeld tells us later in his address: "their second, local government." We now learn that this "first idea" is quite a subsidiary consideration to the latter, even when designed with specific reference to "health"; and that the scandalous failure of the appointments made, on the principles above stated, to secure such a performance of the duties attaching to them as the public had a right to look for, especially in the case of the "higher" appointments of medical officers of health, in no way detracts from their success as examples of local government.

It will be observed how this manner of regarding the question simplifies that "education" of local authorities to which the Local Government Board had addressed itself. It at once eliminates any necessity for knowledge on the part of the Local Government Board, as chief sanitary pedagogue, or on the part of the agents or assistant-pedagogues whom it employed in initiating the Act of 1872, of the subject matters to which the Act related. The ultimate design of the Act was in fact quite a casual and incidental matter, and the last thing to be considered in estimating its successful application. We are now, therefore, quite prepared to understand the charming simplicity of the preparation and selection of the agents empowered to carry out the Board's policy, and the exclusion of its trained and experienced technical staff in mere matters of health from all part in it, whether consultative or active. "Immediately on the passing of the Public Health Act, 1872, before leaving town for the long vacation", Mr. Stansfeld states, "he called together the general (former Poor-law) inspectors of the Board, and, having occupied a couple of days in discussing with them collectively the provisions of the Act, and the policy which he thought it most wise to pursue in initiating local administration, he dismissed them to their districts, there to act as interpreters and negotiators of the Board". The widely different interpretations of the Board's policy by these gentlemen has led to the Board being accused of vacillation and uncertainty. Mr. Stansfeld states that its policy was neither vacillating nor uncertain; and we are left to infer that the general inspectors (weak mortals probably, like ourselves) were unable to rise to the serene heights of political abstraction of the Board, and imported into their counsel with local authorities crude conceptions of the ultimate health aims of the legislation they were initiating, and so blurred the Board's wisdom.

It was really superfluous, after this explanation, that Mr. Stansfeld should take the trouble to further explain the errors of medical men, especially as represented by our Association, in estimating the action of the Local Government Board under his administration. We shall presently refer to the misrepresentation which he makes of the proposed scheme of the Joint Committee of the British Medical Association. That deserves to be treated separately. But, as to the particular point of the relations of the medical staff of the Local Government Board to local health-officers, as he understands it, we would have had medical inspectors entrusted with educating local authorities in their sanitary duties, under the supervision of the "principal medical officer of health"—Mr. Simon, we presume. We plead guilty of thinking, with the Royal Sanitary Commission, that Mr. Simon's "concentrated superintendence of all public sanitary arrangements, whether those of local boards of guardians or any other local authorities, would greatly add to his usefulness and power". Mr. Stansfeld tells us that to have acceded to such a view would have been to commit "a disastrous and fatal mistake". He adds, moreover, that "to maintain the authority

of the scientific man, and to secure for him respect and even popularity, it was necessary to reserve him for occasions when there was a sense that his special knowledge and services were needed". The withholding of this special knowledge, although, in fact, it covered the whole field of public health administered by the Board, and had been matured in the case of the medical staff attached to the Board by an exceptional experience, was held necessary, Mr. Stansfeld tells us, to the success of the public health administration of the kingdom; and we even learn that this was an element in a policy of "respect and trust" towards local sanitary administrations, for Mr. Stansfeld says that it was "not only because local governing bodies of this country could not be driven, but possibly led, that this policy of respect and trust towards local administrations was deliberately adopted".

We learn, indeed, from Mr. Stansfeld, that the Local Government Board under his ministry saw no chance of a successful performance of public health duties, either by itself or by local authorities, except by avoiding knowledge of the subject matter. It was not needed by the former; it would have been an insult to proffer it to the latter. The proper function of skilled knowledge in public health administration, whether central or local, and in the sanitary educational system which the Local Government Board has established, is to rectify mischiefs accomplished, not to prevent them, and to teach from such rectifications. The rights of ignorance must be respected, as well as the rights of knowledge; and the Local Government Board, in the responsible exercise of its public health duties, has been careful to interfere between an assumed aggressive skilled knowledge and the necessary ignorance of sanitary matters of newly created sanitary authorities. It has a pleasing, respectful, and trusting confidence that local administrations will appreciate this consideration for their feelings, and will accept without remonstrance the position of tetchy children confided to unskilled nurses, with little chance of education except through their misfortunes.

THE NAVAL MEDICAL SERVICE.

WE considered it our duty, not long since, to state the actual progress that had been made by the Admiralty towards redressing the numerous grievances of the department that were brought under the notice of the First Lord by the deputation of the Parliamentary Bills Committee of the British Medical Association. We then stated that, in our opinion, it was undesirable that any response should be made by the schools at present, to the notice issued from head-quarters, of an intended examination of candidates to be held next month. We can now only repeat that advice. A semi-official intimation has been given that a warrant has been prepared by the Admiralty and placed before the Treasury, but not a word as to its provisions has been permitted to appear. Consequently, we are entirely in the dark as to its bearings on those already in the service, or what inducement it may offer those about to enter. On a past occasion, when a sufficient number of candidates presented themselves to fill up the present vacancies, the Government of the day, relieved from the pressure, relegated the work of reform to the waste-paper basket.

Young medical men, in their own interest, as well as that of the department into which they might think of entering, will no doubt, therefore, now suspend their action, and wait the course of events. We would also hope that, whatever regulations their lordships may see fit to issue for placing the department on a new basis, may, on this occasion, be carried out in their integrity. The difficulty that has been experienced in keeping young medical officers in the service shows how utterly futile it is to induce young men to enter by holding out hopes and promises that are not to be realised. It is in the public interest that we tender our present advice, not less than that of the profession and the service. We would take, for example, the circular of March 1st, 1874, published for the information of candidates, showing what it promises, and how it is carried out.

PROMISES.

1. Surgeons at home, after completing their time for examination for the rank of staff-surgeon, second class, may be granted two months' leave of absence on full-pay, on condition of their resuming their studies at a medical school or hospital.

2. Promotion to the rank of staff-surgeon is open to officers for distinguished or special service, although twenty years on full-pay may not have been completed. Such staff-surgeons will have 16s. a day half-pay.

3. Staff-surgeons rank with commanders according to date of commission.

4. The whole time served on full-pay as surgeon to be allowed to staff-surgeons, second class, to qualify for the rank of staff-surgeon, provided the examination for staff-surgeon, second class, be passed before the officer completes ten years' service; otherwise, only ten years served as surgeon will be allowed to count.

5. Staff-surgeons are appointed to the flag-ships of commanders-in-chief on foreign stations, with an allowance of 5s. a day in addition to their established pay.

6. The hospital allowances for naval medical officers at home and abroad, in lieu of provisions for themselves and servants, and for fuel and light.

7. The travelling allowances, extra pay, lodging-money, and compensation for losses, are fixed for naval medical officers according to their relative rank in the service.

8. Medical officers have cabins according to their relative rank in the service, excepting always that the senior executive officer, of whatever rank, has the one most suitable for his duties.

REALITY.

1. In not one instance has this been granted that we are aware of, although the regulation has been in existence for years.

2. This promise has been fairly carried out; but, during peace time, the opportunities for gaining this step are reduced to a minimum.

3. In what way this benefits the staff-surgeon, it is difficult to say. He does not enjoy a single advantage that the rank confers. He is not allowed to have even the choice of a servant, as commanders have.

4. Considering that the average time lost on half-pay in completing twenty years' full-pay service is three years, this is no boon, and contrasts most unfavourably with the army, with its continuous service.

5. This regulation has been carried out in the most meagre manner. The staff-surgeon of the first flying squadron was mulcted of the whole amount at the expiration of the ship's commission. At present, the staff-surgeons of the Channel flying squadron have this allowance.

6. This allowance at home is quite inadequate, and abroad contrasts most unfavourably with the allowances given to army medical officers. In some instances, the Admiralty, by designating the establishment "sick quarters", have disallowed the allowances altogether. This has happened at Trincomalee and Portland.

7. This affects naval officers in general so little as to be worthless, but the principle is systematically ignored.

8. It is a downright misstatement of facts to say that the medical officer has choice of cabins according to his rank. He has not. A chaplain of two days' standing will take precedence of a medical officer of thirty years' service; so will a paymaster; and, latterly, the senior marine officer has been placed before him, though he can be only a captain, while the medical officer may have the relative rank of major, and possibly that of lieutenant-colonel. This is considered by the medical officers the greatest insult to which they have yet been subjected.

Then follows the scale of full- and half-pay, with which those interested in the matter will have no difficulty in making themselves acquainted.

While such a state of affairs as this exists, we have little hope that the Admiralty can either get candidates, or retain them. And let our young medical brethren recollect that these are the regulations now in force in the service.

WOODEN HOSPITALS.

WE have received, through the courtesy of Dr. Day of Geelong, an interesting paper on the advantages of freshly-constructed wooden sheds for hospital purposes. This paper was read at the Medical Society of Victoria, and elicited some discussion there; though, to judge from the account furnished to us, that discussion was by no means of a searching nature. Dr. Day's theory is that "certain kinds of wood, such as red or yellow deal, American pine, and white deal or spruce, possess the property of acting on atmospheric oxygen, and converting it into peroxide of hydrogen, a substance remarkable for its power of destroying the offensive products of decaying organic matter"; and he infers that the exhalations from the walls and roofs of sheds composed of such wood will, by their anti-septic properties, render the putrefying organic products generated by the suppuration or decomposition of wounds harmless. Dr. Day also attributes to the same substance—the peroxide of hydrogen—the property of destroying the contagium of scarlet fever; and states that he has used the ethereal solution of peroxide of hydrogen, erroneously called "ozonic ether", with remarkable effect in staying the spread of that disease. His plan is to anoint the patient's body three times a day for a fortnight or three weeks with this ether mixed with lard in the proportion of one part to eight; and he points out that the greasy substances which are used to check the spread of scarlet fever, and whose action is believed commonly to be merely mechanical, themselves absorb oxygen from the atmosphere, and convert it into peroxide of hydrogen. The only facts which Dr. Day produces in support of the general assertion with which he begins his paper—that "certain diseases, such as pyæmia, erysipelas, and puerperal fever, which are so common and so fatal in ordinary hospitals, rarely, if ever, occur in hospitals constructed of wood"—consist of a statement by Dr. Shrimpton, taken from the *Lancet* (April 4th, 1874), that in some huts at Shorncliffe and at Colchester there had been at the former place "702 deliveries without any death from puerperal disease" and at the latter "202 deliveries had been registered, but no deaths"—a statement too vague, and admitting of too many explanations to be worth much to his argument; and, secondly, of an extract from the *Medical Times and Gazette* (December 13th, 1873), recording a visit which Dr. D'Espine made to the hospital at Leipzig, which seems recently to have been converted into a collection of fourteen wooden sheds enclosing a stone building, the old hospital, "which now is exclusively devoted to paying patients, who have each their separate room". In these wooden sheds, it is said that Professor Thiersch performed 266 serious operations during the twelve months from August 1872 to August 1873 without losing a single case from pyæmia; while, prior to the construction of the shed-hospitals, he lost from forty to fifty amputations from this cause annually. But we are not told how many beds the old hospital contained, nor in what space these beds were placed, nor what were the arrangements of the building. And the enormous number of amputations said to have been lost annually from pyæmia really renders a statement of these matters necessary. We presume Professor Thiersch did not lose every patient whom he amputated, and also that his patients sometimes died from other causes than pyæmia. If this were so, we can hardly estimate the number of amputations performed annually in this hospital (even allowing, as we suppose is the fact, that Professor Thiersch performs every amputation which is done in it) as less than one hundred—a number of amputations more than twice as great as those performed in one year at St. Bartholomew's Hospital. In fact, if we follow Mr. Bryant's calculation (see *Medical-Chirurgical Transactions*, vol. xlii), that pyæmia is the cause of death in 42 per cent. of fatal amputations only, we should estimate the fatal amputations by themselves at above 100. If Professor Thiersch was so unlucky as to lose every other amputation, this would raise his total to

the startling number of 200. In the last volume of the *St. Bartholomew's Hospital Reports*, it seems that forty-four amputations were performed there in the previous year, reckoning only those of the limbs, which is what we suppose to be intended here. If this is about the usual average number of amputations in a metropolitan hospital of six hundred beds, it would certainly be desirable to have more definite information as to the size, circumstances, etc., of an institution at Leipzig in which from three to six times as many similar operations were performed. And until we do receive more precise data, we may as well infer that the improvement in the results of amputations (allowing it to be real) was a consequence of a better proportion between the space allotted to patients and the number of large wounds, or to any other hygienic improvement as to the change in the material of which the walls were composed.

We merely instance this as an example of the vague kind of evidence on which these general propositions in hospital construction are ordinarily supported. Otherwise, Dr. Day's suggestion is a reasonable one—that wooden sheds may *per se* have some advantage over stone walls in generating some substance analogous to turpentine, which may purify the atmosphere. Whether that advantage is enough to balance the disadvantages which must attend the treatment of disease in sheds, which can be only imperfectly warmed and ventilated, we require much more experience than has as yet been obtained before we can even guess. Writers on this subject are apt to speak of the treatment of patients in sheds "exposed to all the winds of heaven" as if that were really an advantage. The common sense of mankind is at one, however, with all medical experience in concluding that cold and draughts are fruitful sources of mischief both in health and in sickness. If Dr. Day be correct in saying that erysipelas is ever generated by washing the floors of hospitals—which our London experience decidedly negatives, in spite of the respectable authority which can be quoted for it—we would say that erysipelas is generated much more commonly by exposure to a cold blast of east wind; and, even if peroxide of hydrogen could be proved to have ever such active qualities in "destroying the offensive products of decaying animal matters", we must own to a preference for the old-fashioned oxide—pure water—to wash them away.

It is really impossible to form any opinion as to the relative goodness of various materials for hospital construction, till our reformers will condescend to be a little more particular in comparing cases whose circumstances are otherwise similar. We have seen no proof as yet that permanent buildings do become unhealthy when the well-known laws of hospital hygiene are observed. Brick or stone wards become, as we know, unhealthy when overcrowded, dirty, ill-ventilated, etc., whether those wards be in country or town, isolated or in a large building; and so, we believe, would wooden wards. At the same time, Dr. Day's paper is worthy of remembrance; and we hope to receive more conclusive and more valuable facts bearing on the subject, on some future occasion, from himself or some other observer.

A CONFERENCE will be held shortly by the Joint Committee on State Medicine of the Social Science and British Medical Associations, for the purpose of issuing a reply to the recent misstatements by Mr. Stansfeld, as to the nature of the proposals made to him by the Joint Committee in reference to the Sanitary Acts.

DR. BARNES has migrated from St. Thomas's Hospital to St. George's, Dr. Clarke having resigned his post of Obstetric Physician and Lecturer on Midwifery at the latter institution. Dr. R. J. Lee remains as Assistant Obstetric Physician. Dr. Gervis, we presume, will be promoted at St. Thomas's to the full appointment; and this will cause a vacancy for an Assistant Obstetric Physician.

DR. MARY PUTNAM JACOB, says the *New York Medical Record*, during the recent meeting of the New York Pathological Society, temporarily occupied the chair during the presentation of a specimen by the President. The same lady read a valuable paper recently on the use of belladonna and nitrite of amyl in spasmodic dysmenorrhœa.

DR. A. E. SANSOM has been elected an Honorary Fellow of the Medical Society of the State of New York.

PRINCE LEOPOLD.

WE would say nothing to add to the general anxiety which the condition of Prince Leopold must necessarily create. Hemorrhage after typhoid fever is always one of the most serious complications. In this case, the attack of fever was slight; but the peculiar liability of the prince to severe hemorrhage, from which he has always been a sufferer, give a special aspect of gravity to his condition. It is essentially a case for vigilant medical attendance and most careful nursing; and, as these have before now saved Prince Leopold from urgent conditions of peril, so we may now hope that they will triumph over the present difficulties. He is in the hands of those who have watched him from the cradle, and who are armed by the special experience of his constitution, as well as the most ample command of professional resources.

THE OUTBREAK OF FEVER AT LEWES.

WE are glad to find that the severe outbreak of enteric fever in Lewes is now practically at an end. The provision of a constant supply of water, instead of the existing intermittent service, resulted, as we have before pointed out, in a rapid diminution in the number of fresh cases; and notwithstanding the fact that there were many centres of infection in the town, the efforts of the authorities, especially in the matter of disinfection, appear to have been eminently successful. The disease having been evidently due to defects connected with the system of water-closets, we are not surprised to hear that an effort is about to be made to induce the population to abandon this means of removal of excrement. A subcommittee of the Town Commissioners have placed themselves in communication with Mould's Earth-Closet Company, and it has been determined that a certain number of houses are, by way of experiment, to be provided with earth-closets, the various arrangements to be under the supervision of the Company; the Committee itself, however, undertaking to provide the dry earth and to remove the contents of the closets. It is stated that the Company have offered the Commissioners the most liberal terms, in order that the system might be fully tested by the inhabitants of the town; and, as the experiment is likely to be carried out under favourable circumstances, it will be interesting to note its results, for hitherto we have had but little experience of the working of this system elsewhere than in public institutions and in villages.

THE CONTAGIOUS DISEASES ACTS.

WE publish in another column a further weighty letter from Professor Parkes, F.R.S., of Netley, proving the beneficial action of the Contagious Diseases Acts. Dr. Parkes is known as one of the calmest and most judicial intellects in the profession, as well as one of the most able, kindly, and clear-sighted advisers whom any department can possess. No man is more thoroughly qualified to settle a question of figures; no man can speak with such weight on a question of medical hygiene. His testimony must go far to settle any controversy in that territory. It was on that ground that Mr. Stansfeld and Dr. Nevins raised a contest: with the facts which have now, in our columns, been placed before them, they can, we imagine, hardly possess any further doubts. Outside the question of medical hygiene we do not here travel. There is one objection, however, not adverted to by our distinguished correspondent that, doubtless, will be brought up again to disparage the statistics of the Royal Engineers: namely, that the returns prove the amount of venereal disablement to have lessened steadily, on the whole, from 1860 to 1874; and that, as the proportion was falling before the Acts were introduced, the diminution can be fairly attributed to this natural decline, and not to the effect of the Acts. The answer to this objection, which *prima facie* appears just, is this. If diminution be due to causes not connected with the Acts, these causes should operate at stations where the Acts are not in force and among corps not subjected to their influence. But the re-

verse of this is the fact. Corps habitually quartered in London are as severely disabled by venereal disease now as they were in the early years of the army-statistical returns: and districts where the Acts are not yet in force maintain a mean ratio of disease as high as ever. According to official returns during the first three quarters of last year, 1874, the Foot Guards stationed in London, a strength of 3,158 men, sent 453 cases of primary venereal sore to hospital, besides 456 cases of gonorrhoea and constitutional syphilis. These make a total of 909 cases of venereal disease from a mean strength for the three quarters of 3,158 men, or 28 per cent. of the force, a loss probably equal to 35 per cent. *per annum*. Nor was the past year much worse than its predecessors; and it is well we should be aware that, while the Engineers and other corps, who have the good fortune to pass their time chiefly in protected districts, have been able to reduce their venereal entries to thirteen or fourteen per cent. of their strength, our crack battalions of Guards have, for the last fifteen years, sent, and continue to send, thirty to forty per cent. of their strength to hospital every year, because they are chiefly quartered in the metropolis, which is unprotected by the Contagious Diseases Acts.

DR. RUMSEY, F.R.S.

DR. RUMSEY's many friends, and indeed every member of the profession to which he has rendered such great services, and which he has so highly adorned, will grieve to learn that, after suffering from severe cerebral symptoms, he is now for some time incapacitated from work of any active professional kind. We fear that the great labour which Dr. Rumsey has undergone for public objects has not served to advance his private professional interests, which he has always subordinated to public ends.

IS TORQUAY RELAXING?

IN a popular address delivered at a local institution, under this title, Dr. Radclyffe Hall says:

"For the pulmonary invalid, the question is not, Is a given climate bracing or relaxing? but, Is it cold, variable, and exciting, such as favours the oncome of inflammation? or, Is it soothing, mild, and anti-inflammatory? Were I to characterise the climate of Torquay in a phrase, I would say, it is soothing and safe: safe, because anti-inflammatory; anti-inflammatory, because mild and soothing. How often have I heard former visitors at Torquay say, 'Torquay is the best place for anything of inflammation'; again, from another, 'I never felt so strong anywhere as at Torquay'; again, 'I never feel up to the mark at Torquay; it is too relaxing for me'. Now, the last remark always proceeds from one who has no organic disease; the other two remarks, usually from those who have. Its soothing qualities are due to its mildness as to temperature; to its equality of temperature between night and day; to the absence of the marked coldness at sundown, so common in other places; and to the invisible moisture in the air. For damp or visible moisture I have nothing good to say, except that a sea-fog seldom does harm. People often inveigh against moisture in the air, as if an over-dry air were not much more hurtful. Ask a New Yorker in his polar winter wind, the north-west—the razor which answers to our east wind when our polar current comes down to the earth—what he would not give for a breath of the soft south wind, with the balm of sea-moisture laden! At Torquay, all the moisture in the air is sea-moisture; for we have no land-water, and our geology is limestone cropping up to the surface, which naturally drains away rainfall by the hilly, cliffy character of the rocks. So long as this sea-moisture is invisible, it makes the air soft and respirable; and it indicates a certain amount of heat in the air, to enable it to render the contained moisture invisible. It diffuses a gentle haze through the air, which gives a Claude Lorraine softness of outline to the landscape, and acts in keeping in the heat like a fine thin cloud, radiating down again the heat which has been radiated up by the surface of the ground. Every one knows that a cloudy night is a warm one; a bright, clear, starlight night, a cold one. By way of a personal illustration that seldom occurs, some years ago I had occasion to go without delay to St. Leonard's. It was in the second week of February. A black quiet east wind was steadily on. I found it colder in London than at Torquay. I slept there, and next morning I found myself at the large hotel at St. Leonard's. Here the cold was bitter, much more trying than in the Strand in London. I slept in London, and returned home the third day, the weather having been unchanged all the time. Below

Bristol, the air became less cold. When I got out at Torquay, the cold was so much less unbearable, that I took in long breaths, and mentally exclaimed, "Why, this is breathing made easy!" Now, consider what ease of breathing implies to a pulmonary invalid. It implies, in a word, that his lungs are doing well.

"There is one subject, not strictly pertinent to the matter in hand, on which I wish to make a remark, because it is not commonly known, and it ought to be both known and appreciated; and that is, that Torquay is peculiarly desirable as a residence for those who are prone to suffer from diseases of the kidneys, and from gout and goutishness—disease which are becoming not less rife in the land: not so much because the town-water is very soft and pure, being merely rain-water filtered through granite from the disintegrated felspar of which it may derive possibly some inappreciable alkalinity, as because of the climate acting beneficially on the skin and on the mucous membrane."

CHARGES AGAINST THE DARWEN LOCAL BOARD.

AN inquiry into the alleged neglect of the Darwen Local Board in sanitary matters has commenced. The Commissioners appointed to investigate the cases are Colonel Cox and Mr. Basil Cane. The inquiry, which affected the general sanitary arrangements of the borough, has been adjourned till Monday.

VOTING AT EPSOM.

THE Charity Voting Reform Association, of 30, Charing Cross, S.W., have issued a very valuable further series of correspondence relating to the monstrous abuse of charity implied in the "voting system" at charities. One letter is from the mother of a candidate for the Medical Benevolent College at Epsom, who writes:

"I most gladly sign the enclosed, having had experience in getting my little boy into the Medical College at Epsom; and had it not been for the goodness of Dr. Jenson of South Eaton Place, I could never have succeeded, though I spent more than sixty pounds in the canvass, and am still paying it off to friends who lent me the money."

POLLUTION OF RIVERS.

SEVERAL members of Parliament, representing Yorkshire constituencies, and others, waited on the Home Secretary and the President of the Local Government Board, on Saturday, to point out the evils arising from the pollution of rivers in the manufacturing districts, and to urge the Government to bring in a Bill on the subject. The right hon. gentlemen expressed their satisfaction at the feeling of the millowners in the matter, and assured the deputation that the Government are sensible of the importance of the question.

PUBLIC HEALTH EXAMINATIONS.

AT the meeting of Convocation of the University of London on Tuesday, a motion by Sir William Jenner was brought forward:—"That, in the opinion of Convocation, it is desirable that a special examination be instituted in this university in the subjects which relate to public health." Sir William, being in attendance on Prince Leopold, was unable personally to support the motion, which was, however, moved by Dr. F. T. Bond, seconded by Dr. Buchanan, and agreed to without a division. Dr. Storrar, the chairman, said the senate would meet to consider a report on the question, and, without attempting to forecast their decision, he might intimate his own opinion that very shortly the object aimed at in the resolution would be carried out. Messrs. A. P. Hensman and G. Serrell moved the following resolution:—"That, in the opinion of Convocation, it is desirable that women should be permitted to take degrees in Arts in this University." Mr. Hensman remarked that Convocation, in May last, passed, by a large majority, a resolution in favour of admitting women to all the degrees of the University; but the Senate had since resolved, that, "while desirous of extending the scope of the educational advantage now afforded by the University to women, they did not feel justified in applying for a new charter for that purpose." "A great part of the education of the country was in the hands of women; why should they not, therefore, be permitted to take degrees, if capable of passing the necessary examinations? They would then at once take a proper position, and meet with the substantial reward which, by their labours, they had pro-

perly gained." Eventually, however, the proposition was withdrawn, as it was urged by several speakers, notably by Mr. Osler, who had had charge of the motion in the Senate, that Convocation would be compromising itself if now it sent up to the Senate a weaker resolution than it had passed in May last. Such a course would weaken the hands of those who had gone to the Senate with a decided policy in favour of granting all the degrees to women.

DR. LOMBARD'S THERMO-ELECTRIC APPARATUS.

WE publish in another column a description of an instrument destined, we believe, to add much to the resources of the physician. Dr. Bastian, F.R.S., writes to us concerning it:—"The instrument is very easy to work with after about an hour's practice, and it yields the most accurate and reliable results in less than a minute. Owing to the careful levelling which is necessary, and to the extreme sensitiveness of the apparatus, there is some trouble involved in taking it from patient to patient in the wards of a hospital. But, as a rule, it is only occasionally that the instrument would require to be used; and then no more time would be needed to bring it into play than is necessary for the proper adjustment of a sphygmograph. In the consulting-room, it may be used with the greatest ease, since, where it is allowed to stand on a particular table, the galvanometer may be levelled once for all, and the conducting wires and thermo-piles may remain attached to the rheostat. The apparatus, thus ready for use, may be protected from dust and injury by a bell-jar. I have already found it of much use in testing the relative temperature of paralysed limbs, and it is likely to prove very useful in railway cases. I have recommended the makers of the instrument to supply with the apparatus a scale by which the degrees of centigrade may be at once translated by medical men into the more familiar Fahrenheit notation. I have also had the lamp and stand cut away from the board, and a proportionately smaller box made for the instrument, with the view of still further increasing its portability. The lamp and stand are, in fact, intended for use in physiological much more frequently than in strictly medical investigations; so that, as they would be only rarely used by medical men, they may be more conveniently packed into a small separate box. The maker would, I think, do well to supply certain instruments without these accessories, which are not intended for ordinary clinical work. The cost as well as the size of the instrument may thus be lowered. It is an instrument of precision of great value, from whose use we shall, after a time, doubtless derive knowledge of much practical importance, and by which we may, in addition, hope to widen the boundaries of scientific medicine."

LIVERPOOL ROYAL INFIRMARY.

AT the annual meeting of the governors and subscribers of the Royal Infirmary, on January 18th, Mr. J. G. Livingston moved a resolution to the effect that no physician or surgeon heretofore appointed or hereafter to be appointed to office in any part of the institution, should be re-eligible after completing the sixty-fifth year of his age, and also that physicians and surgeons should not be re-eligible after having held their appointments for twenty-one years. This was seconded by Mr. Guion, and was met by an amendment moved by Mr. Gibbon, and seconded by Mr. Rathbone, M.P., altering the age to sixty instead of sixty-five, as that was the average age of medical officers after twenty-one years' service. The amendment was carried by twenty-seven votes to six.

THE SCARLET FEVER EPIDEMIC.

AT a recent meeting of the Metropolitan Asylums Board, Mr. Barringer presented the report of the Homerton Asylums, stating that, during the last three weeks, 53 cases had been admitted into the general fever side, 11 had died there, and 80 had been discharged recovered, leaving 177 under treatment, being a diminution of 38 as compared with the number in the hospital at the date of the last report. The Committee had also the gratification of reporting that the scarlet fever epidemic, which had existed during the last five months, had con-

siderably abated during the last three weeks: for only 26 patients suffering from this disease had been admitted into the general fever hospital, and none had been taken into the side lighthouse reserved for the cases, and from which 48 had been discharged recovered since the last report, leaving 45 still under treatment there. Having regard to these circumstances, the Committee considered that they might safely direct that the wards of the latter hospital should be closed as they become empty, and the services of the temporary staff dispensed with. When the hospital was empty, the Committee recommended that steps should be taken to disinfect it, so that it might revert to its original use (that of a small-pox hospital), or be ready to meet any emergency which might arise. The highest number of patients in the asylum from any one district came from Holborn; the lowest from Hampstead, two. The report was unanimously adopted, amid general congratulations that the disease had thus much abated.

THE PATHOLOGICAL SOCIETY OF LONDON.

ON Tuesday evening the Society met in Berners Street, at the altered hour of half-past eight o'clock. There was a very large muster of the Fellows. The new president, Mr. George D. Pollock, occupied the chair, supported by the new secretaries, Dr. Green and Mr. Wagstaffe. In taking his seat, the president thanked the Society for the honour done to him in electing him to follow Sir W. Jenner. It was an honour he thoroughly appreciated, as the Pathological Society was one of the most honourable in this or in any other country. Twenty-five years ago he had filled the office of honorary secretary to the Society, and since then it had increased much in numbers. Such, indeed, had been the increase in numbers, that he ventured to suggest that the term of office of president should no longer extend over two years. At first this plan was desirable enough, but now he thought that annual election was preferable, as the Society numbered many men who would worthily fill the office; but who, under the present arrangements, could never attain to the office till long past their prime. He brought the matter forward on the earliest opportunity, in order that it might be considered ere the next election.

COMPULSORY VACCINATION IN JERSEY.

THE Jersey States met last week, for the first time this session, and at once took into consideration the desirability of adopting stringent measures for grappling with the prevailing small-pox epidemic. Four years ago, when the subject of compulsory vaccination was before the States, it met with a strong opposition, and, after a protracted debate, the Bill was thrown out. Now, many, if not all the most ardent opponents, in the face of the present danger, agree as to the necessity for legislative action being taken. Mr. Deputy Le Cronier introduced a Bill on the subject similar to the English Compulsory Vaccination Act, and it was ordered to be laid on the table and discussed at the sitting on Wednesday, the usual delay being dispensed with in view of the urgency of the case. The Sanitary Regulations Act was brought up for renewal, it having been passed for three years only, and being on the point of lapsing. The House agreed to treat it *d'urgence*, and several important alterations were made in it to make it directly applicable to the existing state of the public health.

SMALL-POX AND MEASLES.

THE *Pall Mall Gazette* has a caustic comment on an unfortunate incident at King's Norton. At the meeting of the King's Norton Board of Guardians on Wednesday, attention was called to the case of a man named Cox, who was admitted into the Small-pox Infirmary by order of the relieving officer. Cox, it appears, was a "servant man", living at King's Heath; being very ill, he was visited by the relieving officer, who thought he "had every appearance of a person suffering from the small-pox". A surgeon also, who was called in to see him, pronounced him to be suffering from this disease, and he was accordingly carried off to the infirmary in the small-pox van. When he arrived at that institution, it was discovered that a slight error had been made. Cox was not suffering from small-pox, but was only afflicted with measles; he was

therefore discharged, and having been in the ward some time, no doubt acted as an admirable channel for spreading contagion throughout the neighbourhood. As one of the guardians truly remarked, "it was a very serious matter"; and what makes it more serious is a fact stated by the master of the workhouse, that this was the third case of the kind which had occurred. Medical science, it is to be hoped, is yet in its infancy if it cannot distinguish between small-pox and measles.

THE LATE DR. LAVAL.

THE death of Dr. Laval, who fell a victim to his zeal in visiting the plague-stricken districts of Tripoli in June last, is announced, in earnest and well-merited terms, in the *Moniteur de l'Armée*, by the French minister of war, in the following order of the day.

"Dr. Laval, surgeon-major of hospitals of the division of Constantia, happened to be in the region of Tripoli on leave of absence, when he learned that a severe disease was raging in Merdj, about twenty hours from Bengazi. Without hesitation, he betook himself to that place, and in several cases ascertained the disease to be plague. The only European and the only physician among a terror-stricken population, Dr. Laval lavished his skilful attentions on the diseased with a zeal and devotion beyond praise; at the same time prescribing for the sick, and superintending all the measures which might in any way arrest the progress of the epidemic and circumscribe it within its foci. These measures contributed largely to preserve the neighbouring population from contagion. Unhappily, being himself seized after fifteen days of incessant work, he succumbed to the scourge, affording even in his last moments an example of the highest fortitude and self-denial. The Vice-President of the Council, Minister of War, points out to the army the noble conduct of this army surgeon, as a worthy continuation of the traditions of devotion which have brought to so high a pitch the true glory of the army medical staff."

THE CONTAGIOUS DISEASES ACTS.

THE following memorial has been in course of signature during the past two or three weeks. It has already been signed by upwards of one hundred and sixty medical practitioners in Liverpool. Additional names are still being added from day to day. The signatures include, with few exceptions, those of the leading physicians and surgeons of the town, the medical officers of the Royal Infirmary, the Northern and Southern Hospitals, the dispensaries and other medical charities, and nearly the entire staff of the Medical School.

"To the Right Honourable R. A. Cross, Her Majesty's Secretary of State for the Home Department."

"It having been publicly stated that, of the medical practitioners in Liverpool, not more than twenty-six could be induced to sign a memorial in favour of the Contagious Diseases Acts, and that at the present time it would be impossible to find twelve medical men in Liverpool who are favourable to the said Acts, we, the undersigned medical practitioners of Liverpool, beg to express our approval of the Acts as at present in operation in seventeen garrison towns and ports in the United Kingdom, and to state that we are not in favour of a repeal of those Acts."

ACTION FOR LIBEL.

IN the Queen's Bench, on Thursday, January 14th, an action for libel was tried before Mr. Justice Quain, sitting in the Bail Court, and a common jury. The plaintiff was Mr. P. J. Lavin, a medical practitioner at Cranbrook, and the defendant Dr. Joyce of the same place. The defendant pleaded not guilty, and that the alleged libel was true in substance and fact. Mr. Francis appeared for the plaintiff; Mr. Sergeant Parry was counsel for the defendant. Before the case was gone into, Mr. Justice Quain strongly recommended, but without success, a settlement out of court. Mr. Francis said that his client was a young surgeon, and now assistant to Dr. Wood of Cranbrook. Plaintiff and defendant were members of the Order of Foresters, and, in July last were invited by the secretary of their lodge to a supper. In reply to the invitation, the defendant, in a letter to the secretary, dated July 31st, 1874, stated that he would have much pleasure in meeting his brother Foresters at the supper with one exception, viz., Mr. Lavin, who, he said—if the facts that had come to his knowledge were true—had acted in a most unprofessional manner by making use of informa-

tion he had derived in his professional capacity, to the great detriment of a respectable family, and grave discredit of a gentleman who had resided four years in the parish. He requested the secretary to read the letter to the Court of Foresters, but reminded him that whatever occurred in lodge was under a rule of the society to be regarded as secret. He (Mr. Francis) admitted, that if a medical man acted as the defendant charged the plaintiff with acting, he would be unfit for the honourable profession to which he belonged, and would be guilty of a flagrant offence. Of that offence, however, the plaintiff was not guilty, or of anything approaching to it. He (Mr. Francis) had made an offer that if the defendant withdrew the unfounded imputation he had made, and apologised for having made it, the action would be allowed to drop, and he would not be even asked to pay the costs. That offer had not been accepted.—Mr. Coakley deposed that he was secretary to the Cranbrook Lodge of Foresters, of which plaintiff and defendant were members. In July last, in reply to an invitation to a lodge supper, he received from the defendant the letter in question. The supper was held on August 6th, and was attended by between thirty and forty members. He read the letter at the Court meeting as requested by the defendant. It was attended by seven or eight members. In cross-examination by Mr. Sergeant Parry, he said that the society had a rule to keep secret the business of the lodges. The letter of the defendant did not come within that rule. He had not up to that time heard anything of the subject matter of the letter.—Re-examined by Mr. Francis, he said that Dr. Joyce had been surgeon to the lodge for six months. Dr. Wood was his predecessor, and now his successor.—The plaintiff was about to be examined, when Mr. Sergeant Parry expressed a wish to consult his client. After a consultation with the defendant, Mr. Sergeant Parry announced that his client regretted having written the letter, and that he was misled by the rumours which reached him, and which, at the time, he thought were traceable to plaintiff.—Mr. Francis said that, all imputation on the plaintiff being withdrawn, he (the plaintiff) would not ask a brother professional to pay costs.—A juror was then withdrawn.

HARVEIAN SOCIETY OF LONDON.

THE annual meeting of this Society was held on Thursday, the 7th instant, when the Council's report gave a good account of the Society's work and prospects. The Treasurer had nearly £100 in hand, and there was a sum of £300 invested in consols belonging to the Society. The report dwelt at length upon the disturbed condition of the Society in the early part of last year, when a matter connected with medical advertising in the daily journals was under consideration, as was reported at the time in the BRITISH MEDICAL JOURNAL. The President's address was listened to with marked interest, and we were pleased to be able to give an abstract of its contents last week. The gentlemen nominated by the Council as officers for the year 1875 were unanimously elected. After the address of the President, a *conversazione* was held, to which microscopes and microscopic objects were contributed by Dr. Cheadle, Dr. Shepherd, Dr. Carter of Leamington, and Mr. H. Power; surgical instruments by different west-end makers; china by Messrs. Phillips, and various objects of interest by the terracotta company. A novel feature of the *conversazione* was an exhibition of pictures, drawings, and etchings executed by members of the medical profession; and, although two or three of our most distinguished doctor-artists were not represented, upwards of sixty works of art were shown on the walls, and several portfolios of drawings were also sent for inspection. Sir Henry Thompson contributed several of his pictures of still life, which have been from time to time seen at the Royal Academy, and one which had the honour of a good place in the Paris Salon of 1874; he also sent some powerful landscapes—one, especially beautiful, of a lock on the Thames by moonlight, and a portfolio of vigorous water-colour sketches. Mr. Pilleau, Deputy Inspector-General of Hospitals, lent a very fine oil picture of Venice, several water-colours, and two portfolios of lovely sketches from Venice and Egypt. Dr. Evershed showed some fine cabinet oil works, chiefly of Sussex

interiors, with well-drawn and solidly painted figures; and he also lent three folios, one containing a complete set of his dry point etchings, another of etchings in the first state, and a third of sepia sketches for etchings. Our profession is singularly rich in etchers, and was, on this occasion, further represented by Mr. Seymour Haden, Mr. Probert, and Dr. Buzzard. The latter gentleman, also, contributed some very tenderly felt water-colour drawings. Mr. Lennox Browne, to whom the credit of suggesting the exhibition and its success is largely due, showed several water-colours. The most interesting to medical practitioners were those recently executed at Aix-les-Bains, which gave a good notion of the beautiful scenery and cloudless sky of this favoured inland watering-place. He also sent some views from the summit of Semnos—a verdure covered mountain of an altitude of nearly 6000 feet, which the physicians of Savoie are endeavouring to make the *Nach-kur* of Aix. From the hotel, which is already built, one has a view of the whole Mont-Blanc range of Alps, and of the lakes of Geneva, Annecy, and Bourget (Aix). The views shown were taken at dawn and sunrise, and were certainly calculated to give a favourable impression of the "Righi" of Savoie. Other drawings were lent by Mr. Walter Leaf. A valuable appendix to this art exposition was made in the shape of some excellent pathological drawings from the collections of Drs. Westmacott, Burdon Sanderson, and Hughlings Jackson; and Messrs. Jonathan Hutchinson and Fairlie Clarke. Messrs. Moira and Haigh exhibited some good photographs, and Messrs. Fradelle and Marshall showed a goodly quantity of their medical series of photo-mezzotints. Looking at the expressive portraits of Dr. Fuller, Dr. Anstie, Dr. Murray, and others recently passed away from us, one could not help regretting that comparatively so few members of our profession are to be found in Mr. Fradelle's gallery. Dr. Braxton Hicks most kindly lent his unsurpassed collection of Wedgwood, cut steel jewellery, etc.

THE UNIVERSITY OF BERLIN.

ACCORDING to the recently issued official return, there were 1,609 matriculated students in the summer session of 1874, which number has become increased in the winter session 1874-75 to 1,824; viz., 134 students of Theology, 624 of Jurisprudence, 276 of Medicine, and 790 of Philosophy and Natural Science. Of the 1,824 students, 1,457 are Prussians, of whom 182 are medical students; 367 are non-Prussians, of whom 94 are medical. The remaining states of the German empire contribute 142, of whom 20 are medical students. German Austria sends 8, none being medical; the remainder of Austro-Hungary 24, two being medical. France furnishes one student of Theology and one of Philosophy. Russia sends 62 students, of whom 42 are medical; Roumania and Switzerland each 14 (3 medical). Great Britain and Greece each sends 8, the latter alone furnishing 2 medical students. America sends 58 students (9 medical), Asia 9 (4 medical), Africa 2 (both medical). The total number of students in the University shows a steady increase. In the summer of 1873, it was 1,590; in the winter 1873-74, 1,757; in the summer of 1874, 1,609; in the winter 1874-75, 1,824. The number in the Faculty of Medicine, however, has steadily diminished; the figures for the four periods above-mentioned being respectively 340, 333, 299, and 276. There are 48 students of Pharmacy and Dental Surgery; last winter, the number was 37, and in the summer only 36. It is rather curious that these subjects are taught in the Faculty of Philosophy and Natural Science, not in that of Medicine.

IRELAND.

THE Council of the Royal College of Surgeons, at a meeting held on the 14th instant, appointed Dr. John Cronyn to the professorship of midwifery, vacant by the resignation of Dr. Sawyer.

THE deaths registered in Dublin, for the last quarter of the past year, amounted to 2,138, or in the proportion of twenty-seven to every 1,000 of the population; and, of these, scarlet fever caused 238, or one in every nine of the registered deaths.

REPRESENTATION OF DUBLIN UNIVERSITY.

THE nomination of Mr. Miller, Mr. Gibson, and Dr. Traill, as candidates, took place last Saturday, when confusion and uproar were in the ascendant. The voting commenced on Monday last, and will terminate this week.

PRESENTATION.

AN address and handsome timepiece, with a purse of sovereigns, has been presented to Dr. Stopford W. Halpin, dispensary medical officer, and physician to the Fever Hospital, Arklow, by a large number of the residents of that locality, "in testimony of his unwearied zeal during the cholera of 1866, and in recognition of his long and successful services, and as an expression of our sense at his rare talents as a painstaking successful physician".

SANITARY MATTERS IN IRELAND.

THE Local Government Board and the local authorities are at war about sanitary administration. The Cork corporation are especially indignant with the Board, which has ordered that body to pay their medical officers better. We are afraid the Local Government Commission are partly responsible for the difficulties with which they of the Board now find themselves surrounded. Their weakness at the outset has given confidence to the local authorities. We are afraid that Sir Michael Hicks Beach has found himself in a similar position to that occupied by a predecessor in office, in *Punch's* famous cartoon of "Lord Morpeth throwing pearls before—aldermen". History repeats itself; and, if Lord Morpeth were transformed into Sir M. Beach, 1874 substituted for 1848, and the scene removed from England to Ireland, our contemporary's cartoon of "Sanitary measures" would exactly suit the present day.

THE REGIUS PROFESSORSHIP OF SURGERY IN THE UNIVERSITY OF DUBLIN.

THE Regius Professorship of Surgery in the University of Dublin is now vacant in consequence of the death of Dr. Adams. Many candidates are spoken of, but we believe the contest will not extend beyond the following four—Mr. William Colles, Surgeon to Doctor Stevens' Hospital; Mr. Porter of the Meath Hospital, Surgeon in Ordinary to the Queen; Mr. Wharton of the Meath Hospital; and Mr. Butcher of Sir Patrick Dun's Hospital. We need scarcely say that all are well qualified for the office, and the new governing body of Dublin University will have a difficult duty in making a selection.

THE SANITARY CONFERENCE AT BIRMINGHAM.

THE conference which was held at Birmingham on the 14th may be regarded as satisfactory in its results. A large attendance of sanitarians and representative men from all parts of the kingdom were assembled. We cannot say that any very novel solutions of the crying sanitary evils of the day were propounded. In all essential respects, the meeting resembled the gathering of the Health Section of the Social Science Congress. Although nothing very new or striking was brought forward, either in the way of facts or of arguments, the objects which the mayor had in view when he convened the gathering seem to have been materially forwarded. These objects were to arouse the country generally to a sense of the crying evils which exist in all parts of the kingdom, and, by opening up the questions fully, to lead the way to further and more important gatherings. Such meetings might do something to settle the disputed points of sanitary science by consolidating, organising, and directing public opinion, secure co-operation of the people, and form a firm foundation, which would serve as the basis of their future action. The mayor proposes to establish a National Sanitary Association for this purpose, which, by annual meetings and conferences, would no doubt effect great benefit by collecting and disseminating the knowledge of the most advanced scientific and practical men, and by securing the united action of all classes of the community in remedying the great evils which exist. The movement is well timed. The session of promised Sanitary Reform is fast approaching, and the Government need a strong reminder that the Premier's motto of *Sanitas sanitatum* must be strictly adhered

to, if the Augean evils which now exist are to be remedied. Should the Government fail in their pledges on this point, the motto will have to be changed to the more familiar one of *Vanitas vanitatum*.

The proceedings on Thursday week were divided into two sections, the first part relating to the sanitary condition of large towns, and the second to the dwellings of the working classes.

THE MAYOR, in opening the conference, said: When he first conceived the idea of summoning such a meeting, he limited his expectations to the hope of gathering together some hundred or so of practical sanitarians, who might be willing to confer with their fellow-workers in Birmingham as to their difficulties, and the means taken to overcome them. Now that between 800 and 900 had accepted the invitation to be present, and at least one hundred corporations and local boards were represented, the whole subject had engaged the attention of the press of the country. The time allotted was too short for the business to be gone through. At the same time, he hoped the result would be, that this meeting would be considered as preliminary and introductory; that it would open the question fully, and lead the way to further and still more important gatherings. There seemed to be a want of the proper sense of the importance of this question in the public mind. We are all, he said, startled by any exceptional calamity; but the evils we have to speak of carry off prematurely not units or tens, or hundreds of individuals, but tens and hundreds of thousands, and the negligence which people practise, because they are perpetually present, become commonplace, and are regarded in a fatalistic manner. It is true, when some exceptional pestilence occurs, like that of Over Darwen, attention is directed to the matter; but, as soon as the cause is removed, we fall back to our original apathy, and, excepting in the special district, nothing is done to prevent the recurrence of similar desolators. And yet, when they recall it in Over Darwen, the occurrence is alluded to as a mere accident. There are hundreds of districts in this country in which the same results may arise at any moment. The usual course in these cases is to throw blame upon local authorities; to say it is owing to their stupidity, or apathy, or selfishness, or indifference, that these results obtain. No argument can be more unfair or more foolish, because, if we are to do anything radical in the way of sanitary reform, it must be by means of those bodies; only through them we can act upon the population. It seems suicidal to bring into contempt and to depreciate the only machinery which can efficiently secure our needs; unfair, because local bodies cannot be much wiser than the constituencies which elect them; and we know that all legislation which is in advance of the sentiments of the people is nearly always a failure. It is fair to say that it is only recently that the legislature has vested anything like sufficient powers, and only very recently there has been anything like a concurrence of opinion and unanimity amongst scientific authorities upon the questions with which we have to deal in reference even to the alphabet of the science; and even now there is considerable divergence of opinion. In Birmingham, for instance, urged by the prevalence of an epidemic of small-pox, we endeavoured to make provision for the isolation of patients in a hospital of our own, but, when we came to select a site, go where we would, we found the most strenuous opposition. We were met by clamour of all kinds from property owners and from the inhabitants of the neighbourhood, who said we were unjustifiably bringing a pestilence into their midst. This opposition did not proceed merely from persons interested pecuniarily in the matter. A memorial was presented, signed by one-half of the medical staff of the town, protesting against the undertaking as being fraught with serious danger to the neighbouring population. Again, the Council had drawn up a series of by-laws for sanitary purposes in connection with the building of dwellings. One of these by-laws provided that houses should no longer be built in this town without thorough ventilation; and in Birmingham, which claims to be at least in the van of all reforms and improvements, there has been the utmost opposition to this particular by-law. He mentioned this to show the nature of the difficulties which local governing bodies have sometimes to undergo before they can successfully carry out schemes of reform. He did not believe that the ordinary public is at all aware of the enormous cost of life which is always going on, or of the frightful consequences sanitary, moral, pecuniary, and otherwise which result from it. It is difficult precisely to formulate this waste. The only bases are the statistics of mortality in large towns. He was well aware that these rates have to be considered with the several conditions of each particular city or place. At the same time, when these rates vary from sixteen per thousand to thirty-eight or forty per thousand, he could not, for a moment, believe that these enormous divergences arise from unpreventable causes. The higher rates must be abnormal, and might be considerably reduced by proper sanitary precautions. The same difference exists not merely in districts but in various parts of the same town. Differences in the death-rate exist in a more marked degree

between different classes of the community. For instance, in the city of Manchester, the average age at death of the upper and middle classes is 38, the average age of the deaths of the working classes is 17. The proportion in Liverpool is as 35 years to 15 years. That is, the well-to-do classes have a lease of life more than double the value of that which falls to the lot of their less favoured fellow-citizens. When we come to consider the infant mortality, the variations are still more striking. In the case of infants under five years of age, of every 100,000 in favourable districts, 2,400 die; in Birmingham, the number is 9,500; in Manchester, 11,800; and in Liverpool, 13,300; that is, in great towns these infants prematurely die in proportion of five to one of the death-rate in exceptionally favoured districts. He could not believe that these discrepancies are a necessary consequence of the natural condition of their lives. The late coroner for Middlesex, Dr. Lankester, estimated that every year there perished from preventable diseases, in England and Wales alone, 100,000 persons, and that estimate was confirmed by others. If you put together all the exceptional calamities which from time to time stir and excite the public mind, by railway accidents, fires and explosions, and all deaths from shipwrecks along our coasts, you will not reach one tenth of this ghastly total of 100,000 persons annually done to death by stupidity and negligence; annually murdered by the neglect of proper sanitary regulations; annually driven out of existence by the ignorance and apathy of the people. These figures are not all. It has been calculated that for every person who dies, six persons might be assumed to suffer from illness, and that the loss to the country is not less than ten shillings per week for each of these sick persons; therefore the pecuniary loss to the country from this cause exceeds £2,000,000 sterling a year. The preventable deaths in Birmingham are something like 3,000 a year—that represents the difference between the actual death-rate and the healthy and normal condition. On the same system of calculation, the annual loss by Birmingham from this cause is £54,000 *per annum*. If we could only induce our population to make these calculations for themselves, we should have little to complain of as to ill-judged parsimony, which saves hundreds of pounds in sanitary precautions in order to lose tens of thousands in the death and ill health of our population. We have to consider also their happiness and their morality, and the circumstances alluded to are fruitful occasions of misery, pauperism, intemperance, and crime. All this disease and death are produced by filthy, ill-ventilated, uncomfortable homes, which, in their turn, drive people to the publichouses and worse places. This is the result of the conditions amid which the people live. What folly it is to talk about the moral and intellectual elevation of the masses, when the conditions are such as render elevation impossible. What can the schoolmaster or the minister of religion do, when the influences of home undo all he does? We have bad air, polluted water, crowded and filthy homes, and ill-ventilated courts everywhere, in the midst of our boasted wealth, luxury, and civilisation. Government provides for criminals in gaol 1,000 cubic feet of air as a minimum, and requires school-boards to provide their scholars 800 cubic feet of air. Those children and criminals, after their confinement or their schooling, go back to their homes in which 300, 200, or 100 cubic feet of air are the maxima. Even the air they have is contaminated by unmentionable impurities and filth, in the dark and dreary courts which exist in all large cities. The dead and living lie together in the same rooms for days; all reverence is blotted out from the minds of the people under such conditions, and common decency is an empty name. Then, when these people whom we have suffered to grow up like beasts behave like brutes, we rush to the Home Secretary, in a blind paroxysm of terror, and ask him to give us the humanising influence of "the lash", to repress the instincts which neglect and indifference had been allowed to develop. In the conference which he had convened, he hoped to learn the views of those practical men who have devoted their lives to the subject, as to the best way of securing the cordial co-operation of the people in our efforts for their advancement and welfare. He was astonished at the extent of the powers which are now placed in our hands; it is not an extension of this power that is required, so much as the will to apply it, and the assurance of the support of the constituents. The work of sanitary reform is a slow process; evils have been accumulating during half a century of ignorance and neglect, and it cannot be expected that we shall remove their results in a moment. We shall be fortunate if our exertions enable us to grapple with the ever-increasing difficulties which are arising in our way; but, as we proceed, we may see our way more clearly, and may advance more rapidly. Of one thing he was certain, that we cannot afford any longer to sit still or stand with folded arms in the presence of so great an evil and so disastrous a mischief. To do so would not only be a shameful dereliction of our duty, but a positive danger, to the state; for there is danger in the continuance of this ever-widening contrast between the

wealth and luxury of a few individuals and the deepening squalor and the wretched misery of a large class of the population. Something must be done, and that quickly, to make life brighter and a little easier for those who now groan under its burden, and for our boasted prosperity to rest upon its only sure foundation—the happiness, the welfare, and the contentment of the whole community.

Dr. HILL, the Medical Officer of Health for Birmingham, read a paper on the Sanitary Condition of the Town, from which it appeared that, from having been regarded as the most healthy of the large manufacturing towns, its total mortality has not only become higher, but it has experienced an extraordinary development of zymotic diseases. From these causes the mortality is greater in proportion to other large towns, which have a higher death-rate. The deaths from zymotic causes last year amounted to nearly 24 per cent. of the total deaths. These grave facts have stirred up the sanitary authority into laudable activity, from which good results were hoped, especially as the chief sickness is caused by the unsanitary condition of the town, and hence by preventable causes. Excluding zymotic diseases, the death-rate is only a fraction higher than that of London, and less than several of the large towns. It becomes, therefore, a matter of practical interest to inquire into the causes of this sanitary decline, and take steps to arrest it. The town enjoys great natural advantages, and might have been expected to be distinguished by pre-eminent healthiness. Yet ignorance, indifference, impatience of increased taxation, and false economy, have brought about a state of things which cannot fail to render it filthy, sodden, and unhealthy; in addition it has suffered from peculiar difficulties. Large numbers of houses have windows which do not open at all, and very many houses are of the back-to-back class, which render a thorough draught impossible; and the want of proper sewer-ventilation is greatly felt, and the sewers themselves are far from being complete, owing to a Chancery injunction; whilst the old-fashioned and abominable middens system, which largely prevails, allows frequently the percolation of the filthy liquid through the walls into the cellars, and frequently into the living-rooms of the adjoining houses. The town-wells, which supply 28 per cent. of the houses, are nearly all polluted by excremental and animal impurities. Finally, there is the want of special hospital accommodation, and the streets were badly kept. Dr. Hill discussed *seriatim* the respective remedies of each of the various evils from which the town suffers.

Mr. D. DAVIES, the Medical Officer of Health for the city of Bristol, read an elaborate paper on the Measures Necessary for the Preservation of Health, in which he dealt with the necessity for the removal of sewage and excretions; not that he considered human feces and other ejecta, when derived from a healthy person, to be in themselves dangerous or liable to become so, but because these are the chief repository of the germs of several of the fatal zymotics, and too frequently, in the present condition of our towns, form a band of union between different communities, by which diseases are interchanged. An ample supply of good water should be derived from a distance, his own experience leading him to believe that all water derived from wells situated near to human dwellings, would become contaminated with human sewage, and become the most constant means of diffusing the seeds of typhoid. There should be thorough isolation in hospital accommodation for infectious diseases, as only by the suppression and extinction of these can we produce the greatest effect on the bills of mortality. When the *variola crina* and the *rinderpest* threatened the cattle, many hypotheses were put forth regarding their origin and nature; but this being a matter which affected the lower animals, and only indirectly the health of man, an enlightened legislation soon brushed away the hypothetical cobwebs. The poleaxe, isolation, and disinfectants did the rest, and these plagues of sheep and cattle were stayed. One of the efficient factors in the arrest of these cattle-plagues—the poleaxe—is obviously inapplicable in our case, but the principle then observed can be fully carried out without it. It is humiliating to think that mankind, although waging war against these zymotic diseases for ages, have met with trifling success, whilst they have discovered how to "stamp out" analogous diseases when threatening the sources of their wealth. An ample supply of disinfectants, and proper house accommodation, were among Mr. Davies's preservative measures. He was strongly opposed to the Scotch system of flats, with common stairs, as he generally found that, whenever a case of small-pox occurred on the ground-floor of a house of this description, it soon affected every family in the house. Glasgow stands pre-eminently forward as a warning to all advocates of the Scotch system of houses without isolation. He considered that small-pox, typhus, typhoid fever, and Asiatic cholera, were under the control of measures at the command of the sanitary authorities, and that an inquest under a medical coroner ought to be held over every death from these diseases.

[To be continued.]

THE PRESENT STATE OF THE ARMY MEDICAL SERVICE AS A LIFE CAREER FOR THE SURGEON.

THE pamphlet on this subject, recently published by Dr. Edward Hamilton, Vice-President of the Royal College of Surgeons of Ireland, (to which we have already briefly referred), is a sign of the times, which, we think, it will be well that those in authority should learn to read aright. For a considerable time past, the Army Medical Service has been chiefly recruited from Ireland, and, some ten years ago, it was a sudden influx from that country which encouraged the War Office to throw into the fire a proposed warrant, giving such advantages to medical officers as they can scarcely hope for even now. When, therefore, we find an unmistakable expression of discontent coming from that very country, it is a pretty sure sign that things are approaching a condition that will soon be unendurable.

The author holds an eminent position in the sister capital, being Vice-President of the Royal College of Surgeons of Ireland, and Lecturer on Surgery at Stevens's Hospital; and he tells us, in his preface, that he has undertaken his present task for the purpose of showing the real condition of the Service, and of dissuading young men from entering it until material changes have been made. Should he succeed in his purpose, the Secretary of State for War will have to deal with the difficulty immediately; for, once the supply from Ireland is stopped, the Army Medical Department will begin to perish from inanition. Dr. Hamilton has evidently taken up the question with the ardour of an enthusiast, and army surgeons owe him a debt of gratitude for the bold and effective manner in which he has stated their case. Not being himself in the Service, and having to trust a good deal to information supplied by others, it was not to be expected he should steer entirely clear of errors, some of which we shall point out presently.

The chief points dealt with are: the disadvantages of the unification system, the inadequacy of the pay, the slowness of promotion, the smallness of the retiring allowances, the absence of special rewards and lucrative posts, and the general sense of insecurity produced by the way in which warrants have been tampered with and privileges withdrawn. Such a list of grievances would be fatal to any system, if not rapidly and effectually redressed.

We will consider each of them in order; and first, the effects of the unification system. Here we think that the author has been led away by the advocates of the old regimental system, which, in its original form, can never be recalled now; and his strictures upon the new system savour more of the bitterness of regret than of anything like real argument. The objects of the unification system were to unite, if possible, the medical officers of the Service more as one body, so that they might look upon the Medical Department as their real corps, and thus increase their influence both for their own benefit and for the good of the Service; to make the system, in time of peace, assimilate as nearly as possible to that which obtains in war; to utilise more the time of medical officers; to equalise more fairly the chances of home service; to give officers larger opportunities of seeing disease and methods of treatment; and to provide for the hygiene and medical attendance of the army as economically as could be done for the advantage of the State. Unfortunately, the warrant of 1873 has secured none of these objects, or has done so only in a very partial and inefficient manner, so that the existing system created by it bears but a superficial resemblance to the real change contemplated by its promoters. Every one expected that vested interests would be respected, and that no man actually in a regiment would be removed from it, except with his own consent. It was also hoped that, as it was obviously the intention of Government to reduce the establishment, and to get more work out of its officers, a higher rate of pay and allowances, with some improvements in rank and prospects, would also be granted. Instead of this, however, the only change was the withdrawal of the rise in the surgeon's pay after fifteen years' service, and the practical abolition of the forage allowance in future. The former was, after a struggle, restored, but in the most ungracious manner, accompanied with threats of reprisals instead of an apology for attempting to deprive officers of their just rights. That much annoyance has been caused and great injustice done, must be admitted; but we cannot too often repeat, that this has not been due to the system of unification, but to the working of the extraordinary document above mentioned, of which no man has been found bold enough to acknowledge the parentage. The objections based upon the difficulties in the way of the disposal of the sick have been plausibly stated by Dr. Hamilton; but they are based upon knowledge from secondhand, and do not by any means represent the true features of the case. There is no reason why a patient in a

field-hospital should get "ill-cooked, unsuitable, and not easily assimilable barrack-rations", neither would there be the smallest necessity for removing a patient in heat-apoplexy to a distant hospital. Indeed, the whole of this part of the pamphlet is based upon a misunderstanding of the question, as may be seen particularly by the question on page 9. "But it is said the old hospitals are to be converted into married quarters. We again ask, Is it intended to increase the already excessive number of women and children that encumber every regiment in the service?" To this we may at once answer, No; but it is intended to give each family a room to itself, which surely Dr. Hamilton will admit is the least that can be given for the barest comfort and decency. As regards India, the changes would not cause so much difference there as at home, even if they were carried out to the full.

In referring to the question of the authority of the medical officers in hospitals, the author ridicules the idea of their being in actual command of their establishments and subordinates, on the plea of their having no training to fit them for it. Here he speaks entirely from the standpoint of a civilian, whose connection with a hospital is only an episode of life, whilst with the army surgeon it is his life. We would ask, What training had purveyors, storekeepers, and commissaries to fit them to command their Army Service Corps; and, above all, what training have apothecaries and dispensers had to fit them to command the Army Hospital Corps? Surely the medical officers are, to say the least, as well fitted for this latter post, and to them the full power ought to belong; the chief mistake having been in taking commissioned officers and making them captains and lieutenants of orderlies, instead of making the latter merely warrant officers, and taking them from the ranks.

Again: why should a medical officer of the rank of major-general be put under a lieutenant-colonel, who not only is of no practical use in a hospital, but actually proposes to step between the principal medical officer and the head of his own department? These things have been abolished in the navy; why should they linger in the sister service? It is quite true that the peculiarities of our army, our vast empire, and enormously scattered stations, render it impossible to have a staff system such as obtains in a great continental army in a high state of concentration, and even the most strenuous advocate for unification must admit that a modification is absolutely necessary for our wants. At the same time, the old regimental system was too expensive, too inelastic, and too impracticable for great emergencies, ever to hold its ground on its original footing. The system in peace ought to be as near as possible to what would obtain in war; and in war one of the first things done is to establish a condition of unification to a very large extent. As to the complaint of some officers about the loss of social status, and so on, we cannot but regard this as simply puerile, and as arguing but little for the self-respect of those who make it; indeed, such a feeling we take to be one of the evil results of the old system, and the sooner it is suppressed the better. A more real loss is the separation from a comfortable mess; but here the officer attached to a corps will be, of course, a member of its mess, whilst at each station messes might be established at the head-quarters for the staff medical officers, who would be no worse off than staff-men were under the old régime.

The inadequacy of pay is a very serious question, and is intimately connected with the question of allowances, the rate of promotion, and prospects of retirement. The increase in actual money granted at different times has been greater than among regimental combatant officers, and this has sometimes been used as an argument against further increase; but the cases are totally different; for, with the medical officer, his actual emoluments are all he has to look to, whilst the combatant has all manner of possibilities open to him. At the present time, young surgeons are attracted into the service by a rate of pay on which they can live at once, and it is only after a time that they begin to perceive how small and slow the advance is, and how much better they might have done in other lines of life, when often it is too late to change. There are several ways in which this might be rectified, but the chief are—a direct increase of pay, a consolidation of allowances, more rapid promotion. All three ought, if possible, to be obtained; but it is almost utopian to hope for them. A direct increase of pay, of, say, half-a-crown a day all round, would require an additional £25,000 a year, which, in the present financial temper of the times, it would be hard to squeeze out of the treasury. A consolidation of allowances, such as is given to the Royal Engineers, would be a great boon, and would put an end to much of the annoyance and loss caused by the capricious and irresponsible proceedings of the Control Department. Acceleration of promotion can only be hoped for by inducing seniors to retire, or by making promotion at a fixed period: the former can only be done by giving bonuses on retirement, or by strictly limiting tenure to a certain period; the latter is being partially tried by promoting batches of men of over fifteen years' service. The service

will, however, never be content until a twelve years' promotion is granted, as in the Indian service, and a limit of years put to tenure of office in the administrative ranks. If a surgeon were promoted to be surgeon-major at twelve years, and at twenty years allowed to rank as lieutenant-colonel, according to date, and not junior as at present, a considerable point would be gained. Then, as the surgeon-general and deputy surgeon-general do practically the same work, it is unnecessary to make promotion from one rank to the other depend upon vacancies. Let a deputy surgeon-general rank as a full colonel at once, and let him become a surgeon-general after five years' service as deputy, with the rank of major-general, and let him be obliged to retire after five years in the highest rank. By this means, a healthy flow of promotion would be established; all retired surgeons-general to be of course eligible for the post of director-general, if within the prescribed limits of age. At present, the retirement of a surgeon-general is £680; we think it would not be at all extravagant to give him £1,000, the pay of a general officer, colonel of a regiment. Similarly, the surgeon ought to be allowed to retire on £1 *per diem* at twenty years, and £1 5s. at twenty-five years; and Dr. Hamilton's suggestion of a retirement even at fifteen years (say, on 15s. a day) is a good one, as it is very difficult after that to get any employment in civil life. Dr. Hamilton discusses the question of promotion at fifteen years' service, as compared with twelve years, and gives two tables corresponding to each system. In each table are given the numbers that would be promoted in any current year (up to 1885), the survivors of those promoted in the previous year, and the survivors of those promoted in the second previous year. The sum of these is then taken as the number in each year drawing promotion, pay, and allowances due to the particular system. The additional pay is 2s. 6d., and the allowances he estimates at 5s. a day—too high a sum, as we shall presently show.* According to his calculation in Table C, the plan of promotion at twelve years' service would cause an increase in the estimates for the next five years (up to 1879, inclusive) of £20,438; but, for the succeeding six years up to 1885, a positive decrease of £11,042, or a net increase of only £9,306 for eleven years, or only £846 *per annum*. To this, he adds £1,692 for allowances, and makes the total £2,538—truly a small enough sum for so great a boon. But even this is unnecessarily large, for the difference of allowances is only 3s.; viz., 8d. lodging money, and 2s. 4d. horse and stable allowance; so that the total would be 5s. 6d., or just £100 *per head per annum*. The above sum ought, therefore, to be only £1873, instead of £2,538. Even this is too much; for about one-third would be paid by the Indian Exchequer, so that the Home Treasury would only be debited with about £1253. This is a result so extraordinary, that one feels at first sight that it must be wrong, as it is utterly impossible that we can give a number of men an additional £100 a year three years earlier, and yet save money. The error arises from a wrong understanding of the facts and of the real import of figures; for the influence does not cease with the years selected for comparison, but continues throughout the rest of the officer's service. The only correct way, therefore, to make the comparison is to carry out the table to the same number of years in the horizontal column as treated of in the perpendicular column, up to the thirty-fourth year of service, when the surgeon must either retire or be promoted, and then compare the results so obtained. It would be too long to do this here; but we have made the calculation, and the following are the real numbers, giving the sums merely for each year.

Table showing the Results of the 12 Years' and 15 Years' System.

Year.	Number of Officers drawing Promotion, Pay, and Allowances.			Expense.*
	On the 15 Years' System.	On the 12 Years' System.	Excess due to the 12 Years' System.	
1875..	25	94	69	£6,900
1876..	51	147	96	9,600
1877..	59	212	153	15,300
1878..	85	237	152	15,200
1879..	113	264	151	15,100
1880..	101	313	212	21,200
1881..	213	316	103	10,300
1882..	235	307	72	7,200
1883..	280	320	40	4,000
1884..	243	339	96	9,600
1885..	274	319	45	4,500

* Average cost for eleven years, £9,306 *per annum*.

There is thus a continuous, though varying, excess due to the twelve years' system, the average annual cost being £9,306, which, according to Dr. Hamilton's estimate of 7s. 6d. *per diem*, would be £12,700, or

* In Table C, page 22, there is a misprint which makes a little confusion. In the fourth column, 113 ought to be 153; the same mistake occurs near the bottom of the page.

about five times his calculated amount. The average would not vary much afterwards; but the amount would increase in individual years, so that the mean of the next thirty-four years (up to 1908) would be about £8,900. By that time, however, the service would have settled down to strict seniority, with a constant excess of a little over £8,000, the difference being simply the extra £100 *per annum* enjoyed by each officer in his thirteenth, fourteenth, or fifteenth years. Another way of getting at it is simply to consider that each candidate, on entering the service, is offered a prospective addition to his pay of £100 after twelve years' service, to last three years: this would be worth about £10 *per annum* throughout his service. Multiplying the number of officers in the Department (about 945) by this sum, we have £9,450, almost identical with the average £9,300 obtained above. Of course, as before mentioned, only two-thirds of this would fall to be paid by the Home Exchequer, or about £6,000—a sum not so great that it ought to stop so highly desirable a boon as the hastening of promotion three years. We have called special attention to this point, because we think it important to correct the mistake into which the author has accidentally fallen, and so prevent it, if possible, from discrediting the rest of his valuable paper. We must say, however, that he is scarcely so careful about figures as he might be; for instance, at page 37, he boldly says that the death-rate of the Medical Department is as three to one of combatants; the real fact being, that it is only as four to three—a very different ratio, although it is still high enough.

Dr. Hamilton has hit upon one most important point, and has taken care to develop it in a very effective manner; viz., the almost total absence of anything like prizes in the medical service, in the way of lucrative posts, special pensions, and the like. In the combatant ranks, on the other hand, there are large numbers of these, a rather copious list of which he details. We have not specially verified his figures; but there is no doubt that the statement is near the truth, and must have cost some trouble to get together. The general result is, that there are posts of extra emolument for combatants in the ratio of about one to four; for medical officers, none. As regards distinguished service pensions, these are for combatants as 1 to 39; for medical officers, as 1 to 193. As regards decorations, there are 850 combatants so distinguished on full and half-pay, and only 34 medical, although a similar ratio would raise the number of the latter to about 90, or nearly three times the existing number. No medical officer is ever raised to the peerage, or even to the grade of grand cross of an order; and all the great civil appointments, governorships, and the like, are utterly closed to him. The very military title he enjoys brings with it no social position, as with the combatant; every one knows the position of a captain or a colonel, but few understand a surgeon-major (often confounded with *sergeant-major*!) We do not advance this particular point as one of much importance, but simply to show that the military title adds nothing to the medical officer, who is simply plain Mr. or Dr. to the end of the chapter. We are thus brought face to face with one of the greatest drawbacks of the public service, and we can easily understand why the pay of the medical officer ought to be much greater than that of the combatant. For the latter, all sorts of possibilities are open, up to the highest posts in the realm; for the former—the medical officer—the pay he receives is his all; once he enters the service, he may rest assured that no amount of professional knowledge, or scientific attainments, or other form of excellence, will avail to hasten his promotion one hour, or add one penny to his purse. Is it a wonder, then, if men become apathetic and discontented? or that the best students will not come forward? The real wonder is, that so much has been done under such dire discouragement. The time, however, is assuredly approaching when some active steps must be taken on the part of the authorities, if the Medical Department of the army is to be worthy of the country. Either the pay and allowances must be largely increased, or, better still, a sufficient number of lucrative posts created, to which men should be appointed for merit only, regardless of mere service or successful longevity.

Another point of great importance is, that some guarantee shall be given that good faith will be kept for the future; that one warrant shall not suddenly take away what another has granted, and that the plain and open provisions of a Royal Warrant shall not be set aside and nullified by confidential letters to commanding officers, as was the case with the famous warrant of 1858. And we may here remark, that those medical officers who are most eager for the return of the regimental system are, perhaps, little aware how well they are playing the game of the military branches. The unification would add largely to the power of the Medical Department, and would proportionately diminish that of the purely military element; this the latter naturally do not like, and, by a return to the regimental system, medical officers might find that they had been made tools of to their own detriment.

At the end of this pamphlet, Dr. Hamilton devotes several pages to an analysis of Dr. De Chaumont's paper in the November number of the *Edinburgh Medical Journal*, on the pay, etc., of medical officers. He has evidently quite misunderstood that officer's statements and figures, and he has also unfortunately allowed himself to be the medium of spreading certain ill-natured sayings of gentlemen who appear to have understood the matter in question as little as he himself. A full reply to all the erroneous statements has been published by Dr. De Chaumont in the *Irish Hospital Gazette* of January 1st, so that we need not take up time in discussing them. Apart from this, however, we cannot but say that Dr. Hamilton has done the army medical officers a signal service by his advocacy of their claims.

SPECIAL CORRESPONDENCE.

PARIS.

[FROM OUR OWN CORRESPONDENT.]

Typhus Fever on Board Ship.—Quarantine at Bordeaux.—Population Statistics of France.—Insanity in France.—Pulmonary Phthisis.—Accidents from Frost.—Opening of the New Opera.

ABOUT the middle of November last, Dr. Jaccoud read a paper before the Academy of Medicine on an epidemic of typhus which he observed on board the *Gironde*, a French mail-steamer, on his way to Bordeaux from Rio de Janeiro, whither he had gone on a visit during the last vacation. M. Jaccoud attributed the disease to badly cured hides, which formed the bulk of the cargo, and which were prepared at La Plata, where the cattle-plague had reigned for several months. The malady in question, according to M. Jaccoud, was perfectly infectious and communicable to man, and it partook of the character of typhoid and typhus fevers at the same time, approaching more, however, to the latter type. Another peculiarity of the disease was, that, although communicable from animal to man, it did not appear to be transmissible from man to man, as during the passage, which occupied twenty days, it only attacked those individuals who were directly exposed to the morbid influence of the raw hides; the health of those of the crew who had nothing to do with the skins, and that of the other passengers, was in a most satisfactory state throughout the passage. The disease was amenable to stimulants, quinine, and cold affusions to the body; the disinfecting measures that were taken to prevent the spread of the epidemic proved of signal service.

At a subsequent meeting of the Academy, Dr. Jaccoud described, in the most eloquent and affecting terms, what he had seen on his arrival at Bordeaux at the Paillac Lazaretto, where passengers of infected ships are landed to submit to quarantine. The state of affairs at the lazaretto was most deplorable, and M. Jaccoud stated that the healthy subjects were not isolated from those suffering from infectious diseases, and that there was no separation between the passengers arriving from countries where the yellow fever prevailed, and those that brought with them typhus or cholera. Such a state of things, concluded Dr. Jaccoud, was a disgrace to the country. This brought down the wrath of M. Fauvel, member of the Sanitary Board of France, who, in spite of the corroboration of the facts by M. Chauffard, repudiated the charges brought forward by M. Jaccoud, and stigmatised the report as a perfect calumny. This is certainly very strong language, and, to say the least, rather unacademical; but I must confess that in France the Academicians, like the Deputies at the National Assembly, are not particularly distinguished for refined language towards one another, though in private society they are the most polished of Frenchmen. Dr. Jaccoud's report was made over to a committee, composed of MM. Fauvel, Tardien, and Le Roy de Méricourt, three well known hygienists, who were directed to investigate the matter. The latter gentleman was appointed reporter, and, although he refuted in most energetic terms the allegations of M. Jaccoud, he was obliged to admit the justice of some of the charges. Dr. Jaccoud, however, was so far victorious, that his report was unanimously adopted by the Academy, and steps are being taken to remedy the evils therein pointed out.

If statistics are not always trustworthy, they are sometimes very eloquent and instructive, as may be seen by the following statement furnished by the *Statistique de la France*, a work which has just appeared, and which treats particularly of the depopulation of this unfortunate country, its causes, its progress, and the moral to be drawn from it. In this work, we find that the population of France—that is, the eighty-six departments that remain of it after the spoil by the Prussians—amounted in July 1872 to 36,102,921; whereas in July 1870, when the war was declared, the population numbered 36,855,178. Setting aside the number annexed by the Germans and the deaths during the

war, other causes are constantly in operation, which have naturally awakened the anxious interest of political economists and of all right-thinking men in France. In 1869, the births exceeded the deaths by 84,206; in 1870, the deaths exceeded the births by 103,304; in 1871—the terrible year of the Commune, after the more terrible war—the proportion is still more marked and heart-rending, the number of deaths having amounted to 444,880! that is to say, instead of an increase at the rate of 0.23 per cent., as in 1869, there is a decrease of 1.22 per cent. of the whole population. It is, moreover, shown that, since 1827, the proportion of births to the amount of population has been steadily on the decline; thus, from 3.11 per cent., it has fallen to 2.66 in 1868, to 2.57 in 1869, to 2.55 in 1870, and to 2.66 in 1871.

Another melancholy fact brought out by the above work is the steady increase of insanity, or, as the French term it, *aliénation mentale*. In 1861, the period from which proper vouchers or authentic information could be obtained, there were 22 lunatics to every 10,000 inhabitants in France; in 1866, there were 23.8; and, in 1872, 24.37. Thus, in eleven years, the proportion of lunatics increased to about two per 10,000 inhabitants. Indeed, there were times during this period when the whole population of France might have been considered insane, if one may judge by their acts. In 1871, when so many insane acts were committed in France, 49,589 lunatics of both sexes were admitted into the different asylums; of this number, 33,448 were affected with simple insanity; 6,450 with insanity complicated with epilepsy and paralysis; 4,577 with dementia, whether senile or organic; 5,114 with idiocy and cretinism. It will be seen from the above that simple insanity forms the largest proportion—about two-thirds of the total number of admissions; the cures are reckoned in the proportion of 6.4 per cent. These figures speak for themselves; they express not only depopulation, but degradation.

While on the subject of statistics, I shall direct the attention of your readers to another picture, which is equally melancholy to contemplate. Among the diseases which affect humanity, there is one that may well be termed terrible, as it spares neither age nor sex, and is to be found in every condition of life, from the king in his palace to the denizens of the meanest hamlet. I allude to pulmonary phthisis, which, notwithstanding its chronic character, its slow progress, seems to defy the best resources of our art. In Paris alone, this affection carries off annually from 7,000 to 8,000 victims. Thus, in 1872, out of 39,650 deaths from all causes, there were 7,436 from phthisis, and, in 1873, out of 41,732 deaths, 7,919 were from this affection. This gives an average of twenty-two a day. But what is most remarkable is, that while, from the improved sanitary arrangements that are being daily carried out for the health of the inhabitants of this great city, the mortality from other causes has been considerably diminished, that from pulmonary phthisis is still in the ascendant.

As you will have learned from the daily papers, the accidents that occurred in Paris on New Year's night from the frost have been the great subject of gossip of the day. I find, by your annotations in the last number of the *JOURNAL*, that there were no fewer than 260 accidents that night in Paris alone. This, I beg to state, is far short of the actual number. I do not pretend to be able to furnish precise information on the subject; but anyone who has resided any time in Paris will agree with me in saying, that the number of accidents that occurred on the night in question would be more likely to be 2,000 than 260, and yet the former, I should say, would fall far short of the actual number: 260 is doubtless correct, according to the official or police report; but there must be some thousands that were not brought to notice, as it is well known on New Year's night all Paris is out, either visiting or in search of pleasure. No one was prepared for such a change, which was very sudden, as the weather, though cold, was fine during the day, and the sleet began to come down only late in the evening. There were a great many fractured limbs, and some deaths from falls: one report stated 1,400 of the former and ten of the latter. The only wonder is, there were not a great many more, as the streets were so slippery, that it was simply impossible for man and beast to make half a dozen steps without falling. Among the 1,400, I may mention the name of Dr. Loiseau, physician to, and member of, the Municipal Council of Paris, who had his leg broken whilst *en route* to see a patient. The same report states that there were fifty or sixty horses that had their legs broken, or had become otherwise disabled on that memorable night. I say memorable, as, from all accounts, such a phenomenon had never before been witnessed in France, not even in the memory of that mysterious individual known as the oldest inhabitant. The *verglas*, that is, glazed frost, is not uncommon in France; but it has never been known to prevail to the extent it did last New Year's night.

The great event of the day is the opening of the New Opera. I do not intend to inflict on your readers a description of this splendid

monument, but simply to observe that, although the hygienic arrangements in it are superior to those of the less favoured buildings, yet they are far from being perfect. The great defect in most theatres here, as elsewhere, is the system of ventilation, by which there is either too great a draught, or the air is improperly distributed. This results principally from the great central lustre, which, when lighted, causes a constant draught through the opening above it in the ceiling, and this necessarily affects the acoustic arrangements of the building, as the sounds from the stage or orchestra are directed upwards towards the opening. This would explain why it is that those who have a good ear for music prefer going up to the boxes near the ceiling, as was Rossini's wont, as they can there hear much more distinctly than those below. This defect has been noticed in the New Opera, as the string instruments of the orchestra are scarcely audible. The seats, I am glad to say, are much more comfortable, or rather, one is more at ease than in the other theatres. Music certainly "hath its charms", and is no doubt an important element in the hygiene of man; but, if one be obliged to be pent up in a seat for four or five hours at a stretch, and that in a stifling atmosphere, he had much better stay at home, if he wish to avoid "colds", rheumatism, etc.

EDINBURGH.

[FROM OUR OWN CORRESPONDENT.]

New University Buildings.—Drainage of the New Infirmary.—Effects of the Cold Weather.—Proposed Chair of Theory and Practice of Education.—Opening of Museum of Science and Art.

THE designs for the New University buildings, which were sent in by four architects on the first day of the year, have been examined by the building committee of the University, with a view to choosing the one best suited for its purpose; but they were found to be so elaborate and good, that it was impossible, as well as undesirable, to decide the matter in a hurry; and two subcommittees were accordingly appointed to draw up a report in writing on their respective merits, from two different points of view. One subcommittee is to consider the comparative merits of the ground plans and arrangements for the scientific requirements of the medical faculty, and to consult on the subject with such of the medical professors as are not on the committee. The other is to report upon the suitability of the various plans for a University Hall, and also on the general disposition of the buildings. The cost of the buildings is limited to £70,000, exclusive of fittings. The whole cost, inclusive of the purchase of the land (about £30,000) is expected to reach about £150,000.

The managers of the Infirmary have been for some time past in difficulties with the townspeople in relation to the drainage and sewer arrangements of the New Infirmary. In the original Bill, powers were taken to carry off the drainage westward into the Lochrin sewer, which is the one nearest to the building; but since then a new and large sewer has been erected to the south-east, in the St. Leonard's district, into which the managers now desire to carry their sewage. This is strongly opposed by the dwellers on that side of the town, who, if this course be persevered in, intend to oppose the Infirmary Bill in Parliament. A meeting of the contributors have requested the managers to come to terms with the town authorities, and obviate the expenses of opposition. This matter stands at present, with no appearance of either party giving way.

A number of people in town and country are still suffering from the effects of cold and exposure for many hours in the blocked-up trains at Falaill and on the northern lines during the great storm and snowdrift of the 1st of January. The general complaint is of great prostration of strength, and of continuing weakness in the back and legs. Several deaths are reported of shepherds and others who were lost in the snow, and died of cold and fatigue.

Some time ago Dr. Bell's trustees offered to the University of Edinburgh the sum of £6,000 towards the endowment of a chair of the Theory and Practice of Education. Subsequently a joint memorial was presented to Government by the trustees and the senatus, praying for a grant of the rest of the money necessary to its adequate endowment. A communication has been received this week, intimating that the Government are willing to accede to this request. The sum the Government intend giving is £5,000, which will bring up the endowment of the chair to £11,000, equal to an annual stipend of £440. This is a far higher endowment than goes with most of the chairs in the University, particularly those of the medical faculty. The appointment of a professor will be made forthwith, so that he may begin his course next session.

Now that the effects of the very severe weather are passing off, there is a considerable decrease in the death-rate of the town; it was 136

last week against 175 the week before, equal to an annual mortality of 34 per 1000, against 44 last week. There is still a good deal of scarlet-fever and diphtheria, but the severity of the epidemic is passing off.

The principal event of the past week was the formal opening of the new wing of the great Museum of Science and Art by the Lord Provost, who celebrated the event by a *conversazione* held on the spot. About two thousand invited guests were present, and the affair passed off most brilliantly. The museum was begun in 1861, after a design by Captain Fowke, who struck out also the original idea of the Albert Hall in London. Part of the building was opened in 1866, and there the work stopped till 1871, when the part just opened was begun. There still remains a wing to be added, at the west end, to make the building symmetrical and finish the design. Estimates for this have already been obtained, and we may expect the building works, to be begun this spring. The principal hall, which was "inaugurated" last week, is 270 feet long, 70 wide, by 72 high, with two galleries, supported on light columns. The result of this addition will be the devotion of a much larger space than could be spared before to the natural history collection, which is one of the best in the United Kingdom, and is admirably arranged for the purposes of study. The rest of the building is used for the display of objects illustrating Art, ancient and modern, manufactures in all their stages, architecture, engineering, archaeology, and the kindred sciences. The building will doubtless be a source of great attraction to the visitors whom we are expecting at the annual meeting in August.

At two recent meetings of the Obstetrical Society, there has been a long discussion on the use of perchloride of iron in *post partum* hæmorrhage. Most of the speakers were adverse to the use of the drug. A full report of the debate will appear in an early number of the *Edinburgh Medical Journal*.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

C. J. B. WILLIAMS, M.D., F.R.S., President, in the Chair.

ON THE PATHOLOGY OF LUPUS ERYTHEMATOSUS, WITH A DRAWING.
BY GEORGE THIN, M.D.

MICROSCOPICAL examinations of the skin in different stages of lupus erythematosus by Neumann, Giddings, and Kaposi have shown that in this disease there is great vascular congestion around the sebaceous and sweat-glands, more or less destruction of the glands themselves, and cell-infiltration of the surrounding corium. The author had an opportunity of examining the skin of a man who died of the disease in Vienna in 1873, and selected a portion from the inner surface of the second toe, beyond the area of the sebaceous glands, and in which the disease had begun to show itself only for a few weeks before death. He found the sweat-glands, fibrillary tissue, and rete Malpighi absolutely normal in appearance. There was enormous dilatation of the capillaries, most marked in the papillæ and around the sweat-glands, their contours being indicated mostly by the red blood-corpuscles with which they were filled, but the vessels themselves being visible in some of the sections. The small veins were also distended by blood-corpuscles. The condition of the capillary blood-vessels being such as would, if persistent for any length of time, account for all the changes described in the tissues of the skin by the abovenamed observers, and being found in the case of this man to have occurred antecedent to any such changes, the accuracy of the view that lupus erythematosus primarily affects the glands of the skin was put in question. The author believed that in the present state of our knowledge of the pathological anatomy of the disease, which, however, he considered to be very defective, the earliest morbid condition that has been detected is dilatation and distension of the capillaries, and consequently in life stasis of the circulation.

Mr. HUTCHINSON asked the author why he separated erythematosus lupus from others of the common forms. He had not microscopically examined any of the specimens he had seen; but, from close inspection, he was inclined to think the author's account of the microscopical structure right. Mr. STARTIN had long ago recognised this form of skin-disease as lupus sebaceus from the glands being so conspicuous. Lupus presented many varieties, but this form was rare. Probably in lupus all the structures of the skin were involved, though in different degrees. —Dr. DRYSDALE looked upon this as a variety of scrofula occurring in rather young people of bad family history. —Dr. THIN, in reply, maintained the difference of this from other forms of lupus in various ways; he would not call it a scrofulide.

NOTES ON AN EPIDEMIC OF MALARIOUS YELLOW FEVER OCCURRING
ON BOARD H.M.S. "DORIS" SHORTLY AFTER LEAVING PORT
ROYAL, JAMAICA, MAY 1873.

BY LEONARD H. J. HAYNE, M.D., STAFF-SURGEON R.N.

In this communication, Dr. HAYNE gave an account of an epidemic of malarious yellow fever that attacked H.M.S. *Doris* at Port Royal, Jamaica, in May 1873. The first case, the particulars of which were given, together with a temperature chart, was much like a case of typhoid fever. It occurred on the day of leaving port. Next day, two other men were attacked; and one of these cases, in which black vomit occurred, died on the fourth day. During the following thirty days, eight fresh cases occurred. The ship then sailed into a cooler latitude, and, as the air became cool, all the fever cases improved. Eleven fresh cases occurred, but of a milder type. The writer gave his reasons for regarding the epidemic as one of malarious yellow fever, and distinguished it from the milder "marsh remittent fever", concluding with some suggestions as to treatment.

Dr. LAWSON said it was not very easy to distinguish between malarial and specific yellow fever. In this record, there was only one case of pure yellow fever. It was constantly seen that yellow fever was both sporadic and epidemic; and from this arose the belief in the two forms. The other cases were cases of malarial remittent. The vomited matters were green—not black-brown, as in true yellow fever. It had been laid down as a distinction between specific and malarial fevers, that in the former there were albuminuria and suppression of urine, which did not exist in malarial fever; there were also casts in the urine.—Dr. FAYREER believed in no specific yellow fever apart from malarious fever; but some malarious fevers of a virulent kind were, he believed, contagious—or they were believed to be so in India. Remittent fevers also assumed the specific yellow type, even to yellowness and colouring.—Dr. LEGG pointed out that in this, as in other instances, no morbid anatomy of the fever had been given. To this point men's minds ought to be directed, with a view to future contingencies. He also drew some interesting analogies between yellow fever and acute atrophy of the liver.—Dr. DICKER had seen cases of malignant malarious fever, chiefly from the Terai, almost exactly like the yellow fever of the West Indies, with suppression of urine, etc. Jaundice and suppression of urine were, in fact, common to both.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, JANUARY 6TH, 1875.

EDWARD J. TILT, M.D., President, in the Chair.

Hydatidiform Mole.—Dr. JOHN WILLIAMS exhibited a specimen. C. D., aged 30, married two years, never pregnant before, suffered from dysmenorrhœa previously to marriage. She had passed clots since, at the periods. The last catamenia occurred on June 28th, 1874. Morning sickness ensued, and occasional sickness after food. During August, she nursed an invalid, frequently exerting herself in lifting the patient, especially on the 17th, after which the sickness became worse, and the feet and ankles swelled, the œdema gradually extending upwards to the lower abdomen and labiæ, which were enormously swollen. There was no œdema of face or lower limbs. The abdomen was symmetrically enlarged; a tumour having the character of the distended uterus was felt, soft and elastic, but not fluctuating. No fetal heart-sounds were audible, but a placental *bruit* was once heard a little below and to the left of the umbilicus. *Per vaginam*, the tumour could be felt filling the pelvis. The os uteri was high up and tilted forwards close to the pubes, not characteristic of pregnancy. The tumour was softish, as if it contained fluid, and a small triangular swelling filled the hollow of the sacrum. Taken together, they had the characters of a retroverted gravid uterus. The breasts were enlarged, and the areolæ darker than usual, but not characteristic of pregnancy. On the night of November 10th, she was taken in labour, and was delivered the following morning of a hydatid mole, which consisted of a ruptured bag, having the shape of the uterus, containing the vesicles forming the mole. The bag was evidently formed by the decidua, and was about a quarter of an inch in thickness. At one part, it was thick and fleshy, though a section of it presented many cysts; this thickened fibrin was doubtless the imperfectly formed placenta. Slight hæmorrhage occurred once some days before the onset of labour, and severe hæmorrhage at the time of labour, due to placenta prævia. The case was unusually interesting, as the decidua was expelled almost in its entirety, and thus the mode of attachment of the vesicles to that structure was shown. They were arranged like beads on a string, which string was attached to the inner surface of the decidua. This fact favoured the view that the hydatidiform moles were formed by degeneration of the chorion villi; and in this case the degeneration commenced probably soon after the formation of the placenta

had begun.—Dr. ROUTH inquired if there had been any alternation of a watery and a sanguineous discharge.—Dr. WILLIAMS replied that there had been no discharge of blood at all till the patient came to the hospital.

Asiatic Fetus.—Mr. J. ASHBURTON THOMPSON exhibited a specimen of this. The head presented; and, as the labour was tedious, the forceps were applied and the head delivered, but, as was subsequently found, at the expense of the tissues of the neck. The arms were brought down, but still delivery could not be completed. Whilst Mr. Thompson was absent, with the view to obtaining the assistance of his partner Dr. Brunton, two immoderately forcible pains served to eject the fetus. There were two points of interest in the case: one was the frequency with which little expulsive power existed when the uterus was overdistended; and, secondly, that the pressure from above diminished the circumference of the abdomen by forcing a part of the fluid into the thorax; but the traction exerting pressure in the contrary direction increased the circumference by thoroughly extending the lower part of the abdomen, even preventing the whole of that cavity from being utilised in spreading out the fluid.—Dr. BARNES inquired whether the placenta was pale and friable.—Mr. THOMPSON replied that it was.—Dr. JOHN WILLIAMS suggested that the specimen should be examined, as it was not a common one, and was of much interest.—The PRESIDENT requested Dr. J. Williams and Dr. Hayes to examine it in conjunction with Mr. Thompson.

On Prevention of Mammary Abscesses by the Application of the Principle of Rest.—Dr. W. BATHURST WOODMAN read a paper on this subject. The author had been struck with the rarity of mammary abscess in animals, notwithstanding the forced abstinence from suckling which cats and dogs undergo from the drowning of their progeny, and in spite of the great distension of the udders of cows, mares, and other animals when driven to market, or for other reasons separated from their young. Acting upon this suggestion, he carefully abstained from those manipulations and questionable "gentle" frictions which have long been customary in such cases, and with the most satisfactory results. Where an abscess was threatening, in place of employing liniments, he enjoined perfect rest, the avoidance of all frictions and rough handling and of suckling for a time, if possible, from both breasts, but, at all events, from the one most implicated; the horizontal position, careful application of strips of isinglass, soap, or lead-plaster, or of an air-cushion with a hole in its centre, or of bandages taking their purchase from the opposite shoulder. In addition to these measures, he employed preparations of opium, belladonna, or chloroform applied in compresses, or ice, moist warmth, and leeches. The local congestion was also relieved by diaphoretics, diuretics, and aperients. Belladonna, iodide of potassium, and sedatives were given, if requisite. Illustrative cases of this method of treatment were given, exemplifying its advantages.—Dr. BARNES observed that the principle of rest had long been applied to the treatment of inflammation of the breast. He himself had learned the value of it from Trousseau, when a student in Paris thirty years ago. That admirable physician taught and illustrated it with great earnestness; he placed the breast at perfect rest by carrying strips of leather spread with *emplâtre de Vigo* all round it, so as to lift it well up and exert constant support on the vessels; thus œdema was prevented, and engorgement soon subsided. It must, however, be remembered that this form of pressure was ill-borne in the first inflammatory stage; it was chiefly serviceable when suppuration had taken place and the abscess had been opened; the sac was then rapidly closed. In the earlier stage, he had seen leeches do excellent service. The pressure then must be tighter.—Mr. ASHBURTON THOMPSON said there were two modes of treatment not referred to in the paper, the administration of tincture of aconite, and total abstinence from fluids during the necessary number of days. By giving minim doses of aconite every hour, he had succeeded in cutting short inflammations of the breast which there was no doubt would otherwise have run into suppuration, very frequently indeed, in three cases out of four. In cases of still-birth, he had hitherto found abstinence from fluids sufficient in every case to avoid every kind of mammary disturbance. Ice was allowed in moderate quantity, and no other fluid from the time of delivery until the fourth or fifth day, when the breasts generally returned to their normal state of quiescence. He had had two cases recently, in which this method of treatment had been perfectly successful. The deprivation of fluid caused but little distress.—Dr. BRAXTON HICKS thought the principle of rest had been gradually coming upon us for years, friction only being resorted to among the poor and ill educated. Surgery at the present day was all tending to quietude; manipulation only led to suppuration, and often produced the extra amount of stimulation required to set it up.—Dr. MURRAY observed that the application of a belladonna plaster was of great service, the arm being kept at the same time fastened to the side. In some instances, a slight process of friction up-

wards was productive of good.—Dr. MATTHEWS, whilst heartily assenting to Dr. Woodman's views, thought that the public had largely endorsed his practice, since he had observed that it was a very common proceeding to apply a large lead plaster (spread upon leather) to the breast in cases where it became necessary to get rid of the milk; this, of course, rendered friction and all meddling impossible. He had found that two large and soft handkerchiefs suitably applied—one by way of sling around the neck under the breast; the other in exactly the reverse way, over the breast and tied around the body, so as to include the breast between them, interposing a large pad of cotton-wool to constitute a very efficient mode of applying pressure.—Dr. EDIS remarked that the chief thing to be remembered was to limit the supplies, to act on the bowels, and to ensure perfect rest to the mammae. He was accustomed to order a belladonna plaster to be applied to the mammary region within twenty-four hours of delivery, thus exercising pressure as well as arresting the secretion of milk. Abstinence from fluids and great moderation in diet was enjoined for the first few days, an aperient mixture of sulphate of magnesia and iodide of potassium being given twice or thrice daily to relieve the bowels. The shoulders should be raised and the arms kept perfectly quiet; the upper part of the chest being only lightly covered, and any friction or drawing of the breasts being strictly prohibited. Where this method had been adopted, he had never seen a single instance of mammary abscess. An evaporating lotion continuously applied to the mammae was in some instances sufficient to prevent the secretion of milk; but the pressure obtained from the plaster was of great service, and effectually prevented the employment of any friction.

Labour complicated by Pelvic Tumour and by Convulsions.—Dr. H. M. MANGE brought forward the particulars of a case of this nature, similar in some respects to two other cases he had brought forward, which were recorded in the Society's *Transactions* (vol. iv, p. 129, and vol. xiv, p. 227). The patient, aged 24, short and stout, primipara, when nearly advanced to full time, slipped and fell forward. Labour-pains commenced next day. On examination, the posterior wall of the vagina was pushed forward by a tumour about the size of a large orange, having apparently a smaller mass attached to it. It was hard, but yielding to the touch, and non-fluctuating. The fetal head was arrested at the brim; several ineffectual attempts were made to push the tumour above the brim. Turning was rejected, as the liquor amnii had escaped. Labour went on slowly for four days, when convulsions occurred. Chloroform was administered by Mr. Bailey, and the long forceps applied by Dr. Wells, but without avail. Craniotomy was then performed; and, after considerable difficulty, delivery was accomplished. The tumour, during the passage of the child's head and body, had become forced up above the pelvic brim, and could no longer be felt. It was probably a fibroid attached to the posterior surface of the uterus by a pedicle sufficiently long to enable it to drop into the pelvic cavity. The chloroform acted admirably in arresting the convulsions and keeping the patient quiet. There was no albumen in the urine. The patient made a good recovery.

The Annual Meeting for the election of officers, etc., then commenced. (See JOURNAL for January 9th, page 53; and January 16th, page 87.)

CORRESPONDENCE.

EXPERIMENTS ON ANIMALS.

SIR,—In the discussions on vivisection, the most important practical point appears to me to have been overlooked. I apprehend that no one would contend that experiments on the lower animals are unlawful, however great the pain inflicted, if they be likely to result in the diminution of human suffering. But to inflict pain for the purpose of establishing an important truth, or testing an hypothesis, is one thing; to repeat such experiments over and over again, for the purpose of astonishing a class of students, is another, the truth or the hypothesis having been confirmed or destroyed, and can only tend to tantalise the performer and the spectators.

This opinion is held by members of our profession whose names would carry enormous weight with them; and I conceive that neither science nor humanity would suffer if the law stepped in and sternly forbade the endless repetition of ruthless acts of cruelty for the mere purpose of exhibiting truths already known and admitted.

Vivisections, like executions, should be private—only witnessed by the person who performs them and those whose duties compel their presence.

Your obedient Servant,

Tenby, Jan. 18th, 1875.

FREDERIC D. DYSTER, M.D.

THE CONTAGIOUS DISEASES ACTS.

SIR,—It occurred to me that a good corps to test the operation of the Contagious Diseases Acts in the Army would be the Royal Engineers at Chatham. Although they are a small body, and there is some movement of men coming and going, a considerable number are stationary. The evidence derived from a stationary corps of this kind seemed likely to be particularly valuable. I therefore asked my friend Surgeon-Major Fox, R.E., to take out from his books the number of admissions from primary syphilis and gonorrhœa during the years 1860 to 1874; and this he has most kindly done. The Contagious Diseases Act of 1864 was ordered to be applied to Chatham in the middle of 1865; but I have given the ante-Act period the benefit of the latter months of 1865. Dr. Fox considers that, in 1866, '67, and '68, the Acts were only in partial operation.* The following table gives the mean strength, the total number of admissions, and the ratios per 1,000 of strength. I have also given the number of recruits joining the Royal Engineers in each year at Chatham.

Admissions from Primary Syphilis and Gonorrhœa among the Royal Engineers at Chatham during 15 years. Before the Acts.

Years.	Mean Strength.	Total Admissions.		Admissions per 1000.		Number of recruits who joined in the year.
		Primary Syphilis.	Gonorrhœa.	Primary Syphilis.	Gonorrhœa.	
1860..	896	97	144	108.3	160.7	299
1861..	1013	79	159	77.9	156.9	444
1862..	778	85	139	109.3	178.8	236
1863..	808	87	123	107.6	152.2	311
1864..	868	72	89	82.9	102.5	287
1865..	708	53	73	74.8	103.1	166
Mean.	805	78.8	121.1	93.2	143.3	290.5

Acts in Partial Operation.

1866..	835	69	88	82.6	105.1	431
1867..	1153	114	156	98.8	135.3	350
1868..	1156	73	128	63.2	110.7	309
Mean.	1048	85.3	124	81.4	118.3	383.3

Acts in Full Operation.

1869..	1107	49	90	44.3	81.3	314
1870..	1192	85	109	71.3	91.5	388
1871..	1328	101	128	76.0	96.4	430
1872..	1354	78	94	57.6	69.4	388
1873..	1202	54	84	44.6	69.5	344
1874..	1306	31	83	23.7	63.3	413
Mean.	1270	66.3	98	53.1	78	379.5

These figures speak for themselves. Whether the single years or the means of the two periods of six years before and during the Acts are looked at, the conclusion must be the same. Both primary syphilis and gonorrhœa have been reduced nearly one-half.

To what is this owing? To sanitary improvements? But these troops have been in the same barracks and under the same sanitary system since 1860. To lessened recruiting? The recruiting has been more active in the last period. In neither of these directions can a sufficient reason be found.

It may, indeed, be possible that some of the very great lessening of admissions from syphilis which occurred in 1874 was owing to an order brought into force in the last half of the previous year, which imposed penalties on men with venereal diseases. This may have led to concealment of disease, and to an apparent and not a real diminution. But this cannot account for the lessening in the other years, even if any effect is really to be traced to it—a point I have no means of judging.

Does anything remain except the operation of the Acts to account for the decline of these diseases?

Dr. Nevins has laid great stress on the statement that gonorrhœa has not been affected. It was not in the earlier periods, from obvious reasons; and perhaps it never will be so much influenced as syphilis. But that it has lessened in the Royal Engineers, is undoubted; and I

* Complete registration and regular fortnightly examination of the whole prostitute population was not instituted till the commencement of 1869. See *Official Returns in Minutes of Evidence before Royal Commission*, p. 797.

believe the same effect can really be traced in the protected stations at large.

Dr. Nevins is ready to change his opinions when the evidence is in his eyes sufficient to warrant his doing so. I would now ask him to look at all the Army statistics, and to say what more is wanted to prove to him that these Acts have conferred a most signal benefit both on the Army and on the country which employs and pays that Army.

I am, sir, yours, etc.,

E. A. PARKES.

Netley, January 14th, 1875.

DR. CROMBIE AND HIS PAMPHLET.

SIR,—You will not, I trust, deny me the justice of a few words in your JOURNAL, in reply to an article in the number for Jan. 9th, under the remarkably witty heading of "What Next?" There the reviewer of the pamphlet, *A Plea for the Poor suffering from Painful Incurable Disease*, in his haste to prejudice a most humane proposal, endeavours to cover it up from the sight of your readers under a small cloud of confusion, and runs on contradicting himself from beginning to end in the most pitifully silly manner. Thus: "The only part of the pamphlet in which we concur is the comment upon the inutility of the Cancer Hospital." And then: "Dr. Crombie implies that there are in London only two institutions capable of dealing with cases of malignant disease—the Cancer Hospital and the Middlesex Hospital." Think of the incongruous nonsense of concurring with me as to the inutility of an institution of which he says I imply that it is one of two alone capable of dealing with malignant disease! Again: "Dr. Crombie's proposal rests entirely on an absurd fallacy, because there are innumerable hospitals scattered over the country which already do all or more than he proposes." And next: "In dealing with the class of cases Dr. Crombie seems to have in view, the proper course is to call forth the kindly sympathy and assistance of neighbours and friends, and to allow the local medical man to direct their benevolence as he thinks best." This is "the wise proposal" which the reviewer, with the complacency of superior wisdom, recommends in place of my "unwise one"; for the moment forgetting "the absurd fallacy" and "the innumerable hospitals", which, according to his own account, do all or more than he would now have the local medical man to attempt.

Now, the truth is, the class of cases I have in view cannot, to any intelligent reader of the pamphlet, be a matter of "seeming" at all; for, besides being indicated by the title, it is over and over again distinctly stated that it is persons suffering from painful incurable disease, such as cancer, for whom the medicines are sought; and it is well-known, perhaps to everybody except the reviewer, that not only do the general hospitals not admit such cases, but that they discharge those who become incurable in their own wards.

Enough: those who misrepresent, in order to find fault with their own misrepresentation, and contradict themselves with the utmost indifference, are doubtlessly best left to themselves; and the misrepresentations of this writer are as numerous as his contradictions; but, before dropping the subject, I would just notice that the reference to the Middlesex Hospital, which he thinks must be so offensive to the staff of that institution, is as follows: "The Middlesex Hospital was the first to deal with cancer specially, and, since the days of Sir Charles Bell, has been a nursery for the study of the disease and the advancement of its treatment." If this be not so, I will withdraw my statement, but with regret. The Poor-law medical officers will find, in like manner, that my offence towards them is speaking of them in terms of the highest respect. The reviewer, in fact, has set himself to show that what is, is not; and what is not, is in the pamphlet. If any of your readers choose to read the pamphlet for themselves (which I shall be happy to send them), I am sure they will find more than one point in which to concur with me, where there is nothing advanced but what I believe to be dictated by common sense and humanity.

Yours faithfully,

JOHN M. CROMBIE, M.B.

60, New Bond Street.

* * Dr. Crombie says that he will be happy to forward a copy of his pamphlet on application, and begs that our readers will judge of its merits for themselves. By all means, let them do so. In the meanwhile, we must be allowed to retain the opinion which we expressed last week, that his proposal to send medicines from a central charitable society to cases of painful incurable disease scattered all over the United Kingdom is not a wise one, and that it is not desirable that it should be carried out. It was not, of course, with the words of praise which he incidentally gives to the Middlesex Hospital that we had any fault to find. Far from it. But we demurred to its being classed with the Cancer Hospital, and also to its being said, or implied, that these two

institutions were the only ones in the metropolis where chronic cases of cancer received adequate attention. Dr. Crombie seems to think that we have overlooked the fact that it is *incurable* cases that he has in view; and he reminds us that the general hospitals are not very ready to admit such cases. This, no doubt, is true as a general rule; and yet, as a matter of fact, the metropolitan hospitals, and still more the provincial, do receive, and keep to the end, many cases of incurable disease; while the workhouse infirmaries and sick asylums afford a refuge to a still larger number. We must, therefore, maintain, as we did last week, that the best way of dealing with these cases is to call out the kindly sympathy and assistance of neighbours and friends, and to allow the local medical man to direct it as he thinks best. For one case he may deem the workhouse infirmary the most suitable place, for another the county hospital, for another some invalid home; while private friends and local charity would supply the necessities of the rest. In this way, any case of painful incurable disease can be much more advantageously treated—much more advantageously, both in a medical and in a social point of view—than in the manner which Dr. Crombie proposes.

THE BRITISH MEDICAL BENEVOLENT FUND.

SIR,—We are requested to acquaint you that, at the annual meeting of the British Medical Benevolent Fund, on the 14th instant, Sir George Burrows, Bart., M.D., in the chair, a vote of special thanks was passed to the medical journals for their kind and valuable advocacy of the cause of the Fund during the past year, and amongst these especially to the editor of the BRITISH MEDICAL JOURNAL, to whom the good cause is already so deeply indebted.

In fulfilling so agreeable a duty, permit us to take the opportunity of adding our own very best wishes, and to remain,

Dear Sir, very faithfully yours,

For self and GEOFFREY HETT, M.D. (*Hon. Sec.*)

CHARLES S. WEBBER (*Hon. Financial Sec.*)

1, Upper Berkeley Street West, Hyde Park, W., Jan. 20, 1875.

PUBLIC HEALTH

AND

POOR-LAW MEDICAL SERVICES.

THE Board of Guardians of the Thurles Union have increased the salary of Dr. Quinlan, medical officer of the Borrisoleigh Dispensary District, from £100 to £120 *per annum*.

DUTIES OF MEDICAL OFFICERS.

DISTRICT MEDICAL OFFICER.—In reply to query No. 1, we feel satisfied that the Board of Guardians can compel compliance with the requirement contained within brackets; and we would advise our correspondent to a cede to the same, however distasteful it may be.

2. Should the guardians direct that a medical officer shall periodically visit all persons on the permanent list, even though such persons do not require medicines, we feel that the medical officer has no alternative but to comply; but we would advise that, in any case where such visit has proved to be uncalled for, a representation that such needless visit had been paid should be made to the Board, and their fair estimate of the point be requested.

3. We would advise that immediate attention should be given to every order, however irregularly or unjustly such has been issued; but, if the medical officer feel aggrieved, we suggest that he should submit the facts to the guardians, and request them to direct such alteration as may be just.

4. As regards this query, we hold that it is competent for a medical officer to prescribe for a patient upon the statement supplied by the person who brings the order, provided such person is in a position to afford reliable information; but we would advise that such course should be adopted with extreme caution, and should not avail to excuse the medical officer from as prompt a subsequent visit as it may be in his power to make.

5. As regards the final query, we would suggest that our correspondent should quietly collect instances where the applicants for relief have been advised by the relieving officer to apply to the medical officer for assistance with the view to getting an order for mutton and wine. Very few such cases would, if established, go far to determine the tenure of office of such relieving officer.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following members of the College having been elected Fellows at previous meetings of the Council, were admitted as such on January 14th.

Messrs. Charles Derby Waite, M.B. Cantab. and M.R.C.P. Lond., of Old Burlington Street, diploma of membership dated October 2nd, 1873; and Thomas John Starling, L.S.A., of Higham Ferrers, Northamptonshire, July 19th, 1841.

At the same meeting of the Council—

Messrs. Benjamin Thomas, L.R.C.P. Edin. and L.S.A., Llanelly, Carmarthen; and Edward Lawford, M.D. Aberd. and L.S.A., of Leighton Buzzard, were elected Fellows of the College, their diplomas of membership bearing date respectively May 26th, 1836, and July 1st, 1842.

The following gentlemen passed their primary examinations in anatomy and physiology, at a meeting of the Court of Examiners on the 19th inst., and, when eligible, will be admitted to the pass-examination.

Messrs. William Alexander Molson, Edward Gay Anderson, John Leichtenstein Ritchie, and Robert Addison Stevenson, students of McGill College, Montreal; Constan in Cecil Claremont, Howard Bewley Carter, James Heelas, and Wm. Farewell Blake, of University College; John Ekin Sangster, Henry Charles Procter, and Robert Mercer, of the Leeds School; William John Heslop and Frederic John Livy, of the Manchester School; Ernest Henry Jacob, and Arthur Ernest Powell, of St. Thomas's Hospital; William Price Biden, of the Charing Cross Hospital; Charles Ferdinand Marks, of the Galway and Dublin Schools; Robert Frederick Godfrey, of the Montreal, St. Bartholomew's, and St. Thomas's Hospitals; John Robert Blaikie, B.A. Cantab., of the Cambridge School; Robert Griffiths, of the Dublin School; and George Hugh Snowden, of St. Mary's Hospital.

The following gentlemen passed on the 20th instant.

Messrs. George Thomas Congreve, Sandford Arnott, Wm. Harding Crowther, Sidney German, and Charles James, students of King's College; Richard Lingard Stokes, Paul Haackham, Robert George Edward Willows, and Wm. Ingram Colbin, of University College; Charles Ross Hall, George Henry Cressey, Wm. Henry Webb, and Wm. W. J. Cuthbert, of St. Bartholomew's Hospital; Clarence Richard Gollard, George Bluntell Longstaff, B.A. Oxon., and Kenneth Leander Fenwick, of St. Thomas's Hospital; William Bond Taylor and William Semple Merriman, of the Manchester School; George Richmond Moore, and Frank Willson, of the Newcastle School; George Amos Duke, of St. Mary's Hospital; Joseph Cary, of the London Hospital; and John Todd, of Guy's Hospital.

The following gentlemen passed on the 21st instant.

Messrs. George Adolphus Boodle, Francis Arthur Hailsworth, George Rutland Howat, Hubert Martyn Floyer, Herbert Frederic Chapman, John Winkley Langdon, and Hamilton Lewis Walcott, of St. Bartholomew's Hospital; Edgar John Don Boyd, John Cooper Wilkinson, and Joseph Smith Clowes, of Guy's Hospital; Howard Griffiths Lowe, and George Harcourt Hornsley, of the Birmingham School; George Payne Best, and John Biale, of St. George's Hospital; Henry Seymour Atkinson, of King's College; John Weller, of the London Hospital; Wm. Percival Blackley, of St. Thomas's Hospital; Morgan Henry Lawrence Allen, of St. Mary's Hospital; Joseph Lawes Alleyne, of University College; and Robert Owen, of Charing Cross Hospital.

Sixteen candidates, having failed to acquit themselves to the satisfaction of the Court of Examiners, were referred to their anatomical and physiological studies for three months. The total number of rejections out of the 108 candidates examined, was 44—viz., 15 on the first day, 13 on the second, and 16 on the third day.

Licentiates in Dental Surgery.—The following gentlemen, having undergone the necessary examinations, were admitted Licentiates in Dental Surgery of the Royal College of Surgeons, at a meeting of the Board of Examiners on the 15th instant.

Messrs. Alexander Cartwright, Old Burlington Street, W., diploma of membership of the College dated May 15th, 1874; Jonathan Outley Atkinson, Kendal; William Franklin Henry, Cornhill, E.C.; Simeon Talbot Silvester, Whitgift House, Croydon; Charles James Wallis, Pan, Bases Pyrénées, France; David Watson, Torquay, Devon; George Ratcliffe Kering, Ormonde House, Epsom; Henry Bradnell Gill, Arnold Terrace, Bow Road; and Henry Macleod Hayliss, Oxford Road, Ilkington.

Six candidates, having failed to acquit themselves to the satisfaction of the Board, were referred to their professional studies.

MEDICAL VACANCIES.

The following vacancies are announced:—

ABHYLEIX UNION—Apothecary.
ARMY MEDICAL DEPARTMENT—Surgeons. Applications to be made to the Director General of the Army Medical Department.
ATHY UNION, co. Kildare—Medical Officer and Public Vaccinator. Salary, £120 per annum.
BARONY PAROCHIAL HOSPITAL, Barnhill, Glasgow—Dispenser.
BECKETT HOSPITAL AND DISPENSARY, Earsley—House-Surgeon. Salary, £140 per annum, with furnished rooms, gas, and coals.
BIRMINGHAM AND MIDLAND FRIEL HOSPITAL FOR SICK CHILDREN—Acting and extra-Acting Physicians. Applications not later than February 1st.
BLACKBURN UNION—Medical Officer for the Harwood District. Salary, £25 per annum.
CASTLE WARD UNION—Medical Officer for the Ponteland District. Salary, £20 per annum. Also, the Workhouse. Salary, £10 per annum.
DERBYSHIRE GENERAL INFIRMARY—Assistant House-Surgeon. Board, lodging, and washing, but no salary. Applications to Secretary.
EMSWORTH Groving Factory Surgeon.
ESSEX LUNATIC ASYLUM—Second Assistant Medical Officer and Dispenser. Salary, £100 per annum, with board, lodging, and washing.
FIFE AND KINROSS DISTRICT ASYLUM—Assistant Physicianship. Salary, £100, with board, etc. Apply to Dr. Fraser, Medical Superintendent, Cupar-Fife.
FLUX MILLS FRIENDLY SOCIETY—Medical Officer. Salary, £110 per annum. Applications to A. McKeeman, 7, Hanson Square, Johnstone, N.B.
HARDINGS ONE UNION—Medical Officer for the Brafield District. Salary, £45 per annum.
HARRIS, Parochial Board of—Surgeon. Salary, £60 per annum, including vaccination and medicine for the poor. The gentleman elected will get £20 per annum for attending the ratepayers and cottagers within South Harris. Applications to be made to the Chairman of the Parochial Board of Harris.
HEADINGTON UNION—Medical Officer for the Wheatley District. Salary, £70 per annum.
HULL GENERAL INFIRMARY—Dispenser. Salary, £75 to £100 per annum. Election will take place on the 28th instant.

HOSPITAL F R WOMEN, Soho Square—Surgeon and Assistant Physician.
INDIAN MEDICAL SERVICE—Twenty appointments as Surgeon. Examination in February 1875.
KILCHRENNAN AND DALAVICH, Parochial Board of—Medical Officer. Salary, £60 per annum. Applications, on or before the 30th instant, to W. J. B. Martin, Kilmarnock, Lochgilphead.
KILKENNY UNION—Medical Officer for Kilkenny Dispensary District No. 2. Salary, £100 and fees. Medical Officer for Watchhouse. Salary, £75 per annum. Applications to be sent in on or before the 26th instant.
LEEK UNION—Medical Officer for the Eadon District. Salary, £20 per annum.
LICHFIELD UNION—Medical Officer for the Alrewas District. Salary, £35 per annum.
MIDDLESEX LUNATIC ASYLUM, Hanwell—Assistant Medical Officer.
MORVEN, Parish of, Argyllshire—Medical Officer. Salary, £100 per annum. Applications to H. A. Fraser, Morven, N.B.
NORTH BRIERLEY UNION—Medical Officer for the Seventh District.
NORTH-EASTERN HOSPITAL FOR SICK CHILDREN, Hackney Road, E.—House-Surgeon. Salary, £100 per annum, with attendance, rooms, coals, and light.
NORTHERN COUNTIES HOSPITAL FOR INCURABLES, Manchester—Dispenser. Applications on or before the 31st instant.
NORTH WALES COUNTIES LUNATIC ASYLUM—Assistant Medical Officer. Salary, £100 per annum, with board, washing, and lodging. Applications to be made on or before February 17th.
PLYMOUTH UNION—Medical Officer for No. 3 District.
POPULAR AND STEPNEY SICK ASYLUM DISTRICT—Assistant Medical Officer to the Asylum.
REDDITCH AND DISTRICT MEDICAL ASSOCIATION—Medical Officer. Salary, £150 per annum, with fees and unfurnished house.
ROYAL FREE HOSPITAL—Junior House-Surgeon.
ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City Road—Physician. Applications to be made on or before February 15th.
ROYAL INFIRMARY FOR WOMEN and CHILDREN, Waterloo Bridge Road—Physician.
ROYAL UNITED HOSPITAL, Bath—Resident Medical Officer. Salary, £100 per annum, with board and lodging.
RYDE DISPENSARY—Physician.
ST. BARTHOLOMEW'S HOSPITAL—Assistant Physician.
ST. GEORGE'S AND ST. JAMES'S DISPENSARY—Honorary Accoucheurs. Applications on the 28th instant.
ST. LUKE'S HOSPITAL FOR LUNATICS—Second Clinical Assistant. Board and furnished apartments.
ST. MARY'S HOSPITAL, Paddington—Resident Registrar. Salary, £100 per annum, with board and residence.
ST. MARY'S HOSPITAL—Resident Registrar. Salary, £100 per annum, with board and lodging.
ST. MARY'S HOSPITAL MEDICAL SCHOOL—Medical Tutor. Applications to be made on or before February 1st.
SHEFFIELD PUBLIC HOSPITAL and DISPENSARY—House-Surgeon. Salary, £100 per annum, with board, lodging, gas, and washing.
SMALBURGH UNION—Medical Officer for the Ludham District. Salary, £52 14 per annum.
STRATFORD-ON-AVON UNION—Medical Officer for the Welford District and Workhouse. Salary, £50 per annum.
TENDRING UNION—Medical Officer for the First and Second Districts. Salary, £97 per annum.
TORPHINS in the Parish of Kincardine O'Neil, Aberdeenshire—Parochial Medical Officer: £45 per annum. Applications to Chairman of Parochial Board.
TRINITY COLLEGE, Dublin—Professor of Chemistry: £500 per annum, and fees. Applications to the Rev. Dr. Houghton, Trinity College.
TYNEMOUTH UNION—Vaccination Officer.
ULVERSTONE UNION—Medical Officer and Public Vaccinator for the Coniston District. Salary, £20 and fees. Applications to be made on or before the 25th instant.
UNIVERSITY COLLEGE HOSPITAL—Resident Medical Officer. Applications not later than February 15th.
UNIVERSITY OF EDINBURGH—Additional Examiner in Medicine.
WEST WARD UNION—Medical Officer for the Patterdale District.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.

BIRTH.

SMITH.—On January 6th, at 2, Stanhope Terrace, Gloucester Gate, the wife of Walter Smith, L.R.C.P., of a son.

MARRIAGE.

ARBuckle—BASSETT.—At St. Andrew's Church, Nottingham, on January 19th, by the Rev. Henry Fuller, M.A., Hugh Wright Arbuckle, M.D., of Thorne, Doncaster, to Martha Elizabeth (Lizzie) Bassett, eldest daughter of the late Richard Bassett, of Mapperley Road, Nottingham.

DEATH.

DUDLEY, Edward, M.R.C.S. Eng., at Yardley Hastings, Northamptonshire, aged 40, on January 9th.

UNIVERSITY INTELLIGENCE.

UNIVERSITY OF CAMBRIDGE.

DR. BRADBURY'S LECTURES.—The Linacre Lecturer of Physiology gives notice that he will resume his lectures on Pathological Anatomy on Tuesday, January 26th, at 10 A.M., and continue them on every succeeding Tuesday, at the same hour, throughout the term. The subject of the lectures for the Lent Term will be the Pathology of the Blood-Vessels and of the Organs of Respiration.

OPERATION DAYS AT THE HOSPITALS.

MONDAYMetropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

TUESDAYGuy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

WEDNESDAY ..St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

THURSDAYSt. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

FRIDAYRoyal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.

SATURDAYSt. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—East London Hospital for Children, 2 P.M.—Hospital for Women, 9.30 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M.—Royal Free, 9 A.M. and 2 P.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY.—Medical Society of London, 8.30 P.M. Mr. Richard Liebreich will show a new instrument for operating in Fistula Lacrymalis; Mr. Braine will give Notes of a Case of Hysterical Anæsthesia; Dr. L. S. Forbes Winslow, "On Religious Insanity".

TUESDAY.—Royal Medical and Chirurgical Society, 8.30 P.M. Dr. Theodore Williams, "On the Temperature of Phthisis Pulmonalis, and on the various conditions influencing it".

WEDNESDAY.—Hunterian Society, 8 P.M. Dr. Burton Brown, "On the Poisons of Northern India".

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with *Duplicate Copies*.

AUTHORS desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor: those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

PUERPERAL INFECTION.

SIR,—Would some of the readers of the BRITISH MEDICAL JOURNAL inform me what means they generally use to stop the spread of puerperal fever, and how long it is before it is safe for one to attend cases? I have used disinfectants of all kinds for washing purposes, etc., changing my entire clothing, and all of no use. An answer will oblige.

I am, etc., OBSTETRICUS.

ASSOCIATE, KING'S COLLEGE, AND DR. R.—The portrait of Sir William Fergusson is in the hands of the engraver, and we believe that a copy of the engraving will be presented to each subscriber.

MANAGEMENT OF THE DENTAL "NERVES".

SIR,—I entirely endorse the opinions expressed by Mr. W. Donald Napier relative to the desirability of preserving the "nerves" of the teeth. After an experience like his of twenty years' careful observation, I hold that the destruction of the "nerve" is not attended by such success as would warrant an indiscriminate persistence in its practice, and I think that those who hold views opposed to that practice have reason on their side to support them.

Consider what it is that some so ruthlessly destroy; the so-called "nerve" is the remaining unossified portion of the tooth-germ, whose deuterogenous functions are only in abeyance—only waiting favourable conditions to awake from its dormant state and form new tooth bone, and this it is that many propose, though irrationally, to destroy. But what is the result in a vast percentage of cases? The tooth so treated becomes a dead member, and local irritation speedily calls for its removal. We will allow that, in a great many cases, this pulp comes before us decomposed and disintegrated, and then it becomes the duty of the dental surgeon to remove those putrescent remains, to restore the cavity to a healthy state, and to put the tooth into as favourable a condition for preservation as its wrecked circumstances will permit, and the chances are that it may be serviceable for a time; but the simple exposure of a pulp should never be followed by its unscientific destruction, for it is the centre of a tooth's vitality, and, by rational treatment, may be retained for years as a sound and useful organ.

I am, Sir, yours obediently, T. CHARTERS WHITE.

39, Pelgrave Road, S.W., January 12th, 1875.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

CORRIGENDA.—In the report of the meeting of the Pathological Society on December 1st (see page 14), Mr. Hulke, in reference to his remarks on Mr. Butlin's case of Chondroma of the Lacrymal Gland, wishes to have his remarks put as follows. "After removal of the lacrymal gland, the surface of the eye remained moist, and he had observed the same in two cases of true lacrymal fistula; when the secretion of the lacrymal gland dribbled away through a fistula in the upper eyelid, the result of a wound." In his case of Popliteal Aneurism, in answer to a question put by Mr. Marsh, it is said that two tourniquets were used, one above the other below the aneurism. It should have been "one above, the other below, the groin." In the report of the meeting of the Clinical Society in the same JOURNAL, Mr. Hulke wishes his remarks, in reference to Mr. Teevan's case of Subcutaneous Urethrotomy, to stand thus: "That Sir W. Fergusson was in the habit of using a catheter-staff many years ago—some twenty, when he was at King's College Hospital; that he had very long ago had a set made for himself, after Sir W. Fergusson's model; that he frequently had used them in perineal section of the urethra in the theatre of the Middlesex Hospital; and that they had been frequently copied for other surgeons who had witnessed the advantages they offered." In the report on Mr. Holmes's case, Mr. Hulke writes also that he said that "Nelson showed him three cases where, as a preliminary measure, he split the palate a few days before excising the polypus; and that in these cases the edges of the split palate were sloughy". As he did not watch these cases afterwards, he could not know that deformity was apt to follow this procedure.

THE SHIP "FORFARSHIRE"

SIR,—In reading the JOURNAL of the 9th instant, I saw an article headed "A Terrible Situation". You were doubtful whether the ship carried a doctor. She did; and, in addition, she carried an apothecary, a native of Calcutta. I do not know whether there was a medical examination. Before the coolies came aboard at the wharf, the inspector had them all in a row, examining their mouths; but I am not surprised at cholera breaking out, when nearly a third of them had syphilis or gonorrhœa. I am sure there was no fault about the sanitary arrangements of the ship, for I have been sailing two years in her, and have taken over five hundred emigrants to Wellington, New Zealand, one voyage, and the same number last voyage to Adelaide, and I never had more than four or five deaths.—I remain, yours very truly,

HUGH LLOYD.

ARMY MEDICAL DEPARTMENT.—The late Mr. G. J. Guthrie was elected President of the College of Surgeons three times: viz., in 1833, in 1841, and again in 1854. He was elected a member of the Court of Examiners in 1828 with Mr. J. P. Vincent.

MEDICAL DEGREES AND TITLES.

SIR,—As one who is not an adversary of L.K.Q.C.P.I., I beg to attempt to throw a ray of light on his arguments, as they have not been answered in last week's number of the BRITISH MEDICAL JOURNAL. He wished to elicit the views of some "energetic M.D." who should prove conclusively to him that he is not a "doctor" at all, but perhaps a baker or a tinker. Now, without attempting to establish the latter part of his expectations, I beg to attempt a refutation of his sophistry, as one of the "very few M.D. men" who do see why an "M.D. man" is more a Dr. than a Licentiate of a College of Physicians. A doctor is the highest degree which an university can confer, implying ability to teach and profess the most perfect knowledge of medicine, law, or divinity. The degree in these faculties confers essentially the legal and moral right to display theoretical and practical knowledge in these sciences; and if those who never receive an university education, merely acquiring the minimum amount of knowledge sufficient to satisfy a Board of Examiners that they are not wholly ignorant of the uses of medicines, and the power to administer them, are to be considered doctors, learned in the highest degree, there would, I think, be no need of degrees at all. Your correspondent reasons in a syllogistic form apparently. He assumes that all physicians are doctors. L.K.Q.C.P.I. is a physician, therefore, he is a doctor. But his major premiss is manifestly false. Physicians are not doctors; they are merely licensed to practise medicine, having shown sufficient knowledge of the subjects pertaining to the science to warrant their being allowed to deal safely with the public. It will hardly be questioned that all "medical doctors" are physicians, a doctor's degree implying a thorough ability to teach, practise, and profess the science for which the said degree is conferred. But it would be manifestly illogical to infer the truth of the converse; viz., that all physicians are doctors, since affirmative propositions do not distribute the predicate. There are degrees in surgery as well as in medicine. A Master in Surgery is supposed to be a professor, thoroughly trained in the theory and practice of the art. Such an one is a surgeon; but one may be legally and morally entitled to the appellation of surgeon without obtaining the highest degree, just as one may be a physician without necessarily being a doctor. It is so with the Civil Engineer; his university education and the taking of a degree implying perfect knowledge, and the highest legal authority for the due exercise of the profession. Unfortunately, many assume the title who are permitted to do so with manifest injury to the community. A lieutenant is truly an officer, but every officer is plainly not a lieutenant. No one would affirm that, because a sergeant is an officer, he is therefore a lieutenant. Bakers and tinkers have sometimes assumed the office of itinerant physicians; but no one is justified in inferring from this that your learned correspondent is either a baker or a tinker. The physician should, therefore, be content with the title he has really won, and not assume that to which he is neither legally nor, in a strict sense, morally entitled. To be a doctor and to act as a doctor are two different things.

This longing after the degree of M.D. plainly indicates its high importance, and it is this craving to obtain it without due merit that has tempted unprincipled vendors of degrees to this country, and has made it necessary for you to expose the venal system in your excellent article on Medical Titles.

I am, Sir, yours etc., LEO, M.D.

Merthyr Tydfil, January 11th, 1875.

SIR,—L.K.Q.C.P.I., in the JOURNAL of the 2nd instant, says: "I will not only lay claim to the prefix of 'Dr.', but I assert that I am a doctor legally and morally." As this struck me as being strong language, I sought a very high authority, and I believe, legally and morally, L.K.Q.C.P.I. is right. Let us take a logical and common sense view of the subject. A Licentiate of a College of Physicians is as certainly a physician as a Licentiate of a College of Surgeons is a surgeon. Dr.

Johnson says, under the word "Doctor," "a physician—one who undertakes the cure of diseases"; and the learned Doctor quotes examples of this use of the word from Shakespeare, Dryden, Collier, and Swift. If, then (and I presume the authority of such names is sufficient), doctor and physician are now, and always have been, synonymous in the English language, and they are convertible terms, every Licentiate of every College of Physicians is rightly and legally a Doctor; and if so, why should he not call himself so? There is no law in England more powerful than the law of custom. It makes a permanent highway through private property; it governs parliamentary discussions, and becomes *de facto* a law itself. No doubt it governs the term "Doctor," in its strict etymological meaning, refers only to the degree of Doctor, as the holder of such degree formerly was only one qualified to teach the Faculty to which he belonged (*vide* Dr. Johnson, edition 1785). But the majority of the M.D.s of the present day are not qualified to teach, and none of them would like to be restricted to their strict position. Custom has made the doctor (M.D.) a physician, and custom has called the physician a doctor, so that I believe L.K.Q.C.I. is legally and morally right. In any case, I should expect that those who hold a different opinion can quote as high authority as I have done, for hitherto each writer has given only his own *ipse dixit*.

In conclusion, relying on the law of custom—"Ecos—Lex non scripta"—I shall continue to consider myself morally and legally a Doctor, the more so as the title is freely and gratuitously accorded to me. In fact, did I object to the name, I should be overruled by public opinion; and I must say I think it would be a wise and courteous proceeding on the part of the M.D.s if they would, as a very small minority, gracefully bow to the voice of custom and public opinion, and cease to endeavour to deprive their brethren without enriching themselves; bearing in mind that it was the same gradual change in the habits and customs of Great Britain that set them free from their purely doctrinal office to compete with those engaged in the practice of medicine, and that gave those practising the science of physic the title which once only belonged to the teacher of it—a change that afforded to the one a means of living by his profession, to the other a name to the profession by which he lives; an interchange, so to speak, of two properties, in which I think the M.D. has decidedly the best of the bargain.—Your obedient servant,

ANTIQUE MOS.

SIR.—A great deal of correspondence has taken place respecting the propriety of L.R.C.P.s assuming the prefix of "Dr." What would you recommend a L.R.C.P. Ed. & L., F.P. & S.G., L.S.A., to adopt in a town where a L.F.P. & S.G., and L.S.A., emblazon his name on plate as "Dr. —, Surgeon," etc., where competition exists? Of course the public must think more of a person who adds "Dr." to his name.

L.R.C.P. Ed. & L.

In fairness, please advise, yours, etc.,

* * We advise our correspondent not to imitate his rival in assuming the title of Dr., but to show the public, if it be within his power, that professional skill is of greater value than assumed titles. Two wrongs never make one right.

SIR.—I doubt if any of your correspondents who seem to think it a reasonable demand that the English Universities should confer on them the degree of M.D. after a single examination, however severe, really apprehend the precise position of an M.D. Oxon. or Cantab. Your correspondents have doubtless some idea of the curriculum required for the B.A. degree of the elder Universities. They must know that several examinations have to be passed, and between three and four years of study under special teachers completed; also that the B.A. degree obtained, the student becomes entitled to the degree of M.A. after the lapse of between three and four years; in other words, that it takes seven years to obtain the degree of M.A. This being so, I am sure your correspondents would never dream of asking to be made "Masters of Arts" straight off after a single examination, waiving the matriculation examination, and "smalls" and "mods," and "greats," and "second schools," and, above all, the seven long years of *status* and *proficillaris*. But wait a little: I am writing now of Oxford. Above the degree of M.A. are the degrees of B.D. (Bachelor of Divinity), B.C.L. (Bachelor of Civil Law), and M.B. Imagine this higher grade arrived at by our student; but imagine further, that he desires the highest grade of all—desires to be one of the "Domini Doctores"—then he must still wait on average four years longer, not to mention other tests, before his studying will permit him to be raised to this highest University grade, before he can be a D.D., a D.C.L., or an M.D. Now, your correspondents would never dream of asking to be made M.A.s straight off; nevertheless, in their ignorance of University rank, they demand a degree resting two grades higher. Why do not they petition to be made D.D.s or D.C.L.s straight off, for the jump would be no greater? Your correspondents, evidently think the M.D. Oxon. or Cantab. to be much the same poor sort of thing as many foreign degrees which are granted after a single examination, and at best can rank no higher than an English B.A.; but I trust I have undeceived them. One of your correspondents has written of the Oxford and Cambridge medical degrees as somewhat obsolete. I will ask this gentleman to look at the lists of the Presidents of the Royal College of Physicians, and his respect for somewhat obsolete degrees, I can promise him, will gain notably from its perusal.

Lastly, I must refer to the injustice of your correspondents' demand, amounting as it does to this, that for the pains of one examination they should be hoisted two grades over the heads of those who, like the writer, have for many years been M.A. Oxon.

SIR.—If I remember rightly, about nine hundred men, with what is termed the double qualification, obtained the degree of M.D. at the Scottish Universities during the year of grace. In the town in which I live there are only three medical practitioners, including myself. Three years ago, one of these gentlemen, who has no professional appointment which is not also held by every surgeon in the locality, without any examination whatever, was admitted as Fellow of the Royal College of Surgeons of London. Two friends and myself entered the same day as medical students at Guy's Hospital. One friend and myself passed the Apothecaries' Hall examination the same night. Sixteen gentlemen were examined the same evening, but my friend and myself were the only two who received what was then termed the compliments of the Court. Afterwards, each of us became M.R.C.S. Lond.; but my two friends, who had had no professional advantages more than myself, immediately obtained the M.D. of St. Andrew's. I was the eldest son of six children, my father dying when I was in my fourteenth year; therefore, my mother's pecuniary resources were unable to supply me with £40, which my two friends told me the degree, with travelling expenses, etc., had cost them. Thus circumstanced, I began life with the double qualification only; but in 1860, I took the L.R.C.P. Ed. by examination, which, if it did not give some professional distinction, is wholly valueless to me. As Licentiates of the London College of Physicians had up to that time been addressed with the prefix of "Dr.," I assumed I was entitled to do the same, and acted accordingly. The Edinburgh College now in its communications addresses me with the prefix of "Dr.," I cannot

suppose the St. Andrew's examination differed materially from the one at the Edinburgh College of Physicians, and conclude that the professional level of many M.D.s is no higher than my own, and therefore am tempted to ask why such a rancorous spirit exists against a L.R.C.P. Ed., while others, in no way superior, are sheltered from attack by only having another colour or form which is expressed by the letters M.D.

If gentlemen who feel aggrieved by the qualification and title of L.R.C.P. Ed. will obtain for them an honorary M.D. from the Edinburgh University, doubtless it would be accepted, and we should cease to hear these fretful cries; but it scarcely seems just to oblige a man of forty-nine years to present himself before an examining board when he has passed many years in the arduous duties of a country practice.—I am, sir, yours faithfully,

F. H. HARTSHORNE, L.R.C.P. Ed., M.R.C.S. L., L.S.A.

Brosely, January 1875.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Birmingham Daily Gazette, The Western Daily Press; The Manchester Guardian; The Ulster Advertiser; The Sussex County Mercury; The Broad Arrow; The Surrey Advertiser; The Bedale and Northallerton Times; The Hackney Express; The Liverpool Porcupine; The Scotsman; The Liverpool Mercury; The Glasgow Herald; The Stroud News and Gloucestershire Advertiser; The Bradford Observer; The Morpeth Herald; The Portsmouth Times; The Western Daily Press; The York Herald; The Sheffield Evening Star; The Brighton Guardian; The Sussex Daily News; The Wrexham Advertiser; The Newton Directory; The Sussex Coast News; The Berkshire Chronicle; The Hull News; The Southern Times; The Worthing Intelligence; The Hampshire Telegraph and Sussex Chronicle; The Sheffield Daily Telegraph; The Hereford Times; The High Peak News; etc.

COMMUNICATIONS, LETTERS, ETC. have been received from:—

REPORTS

ON THE

CHEMISTRY OF THERAPEUTICS.

BY

JOHN G. MCKENDRICK, M.D., F.R.C.P.E., F.R.S.E.,
Lecturer on the Institutes of Medicine, Edinburgh.

I.—PRELIMINARY.

It is the object of these papers to point out and illustrate the influence which a knowledge of the facts and laws of chemical science have, or ought to have, upon the practice of therapeutics.

At present, this department of medicine partakes more of the character of an art than of a science. It is wanting in precision, both as to facts and as to general principles. Many isolated facts have been observed, and even ascertained by special means and appliances to be true, but few generalisations have been made. The backward condition of therapeutics may be partially accounted for by the fact that, until recently, the actions of remedies have not been systematically investigated in the light of physiological research. The actions of supposed remedies have been often loosely observed and registered, much in the same manner as the early physicians investigated the phenomena of natural philosophy. But the recent remarkable development of physiological science, with the aid of chemistry and physics, and the introduction of new methods of observation and of instruments of precision, have rendered it necessary to reinvestigate the actions of all physiologically active substances. This work has been taken up, and is being assiduously prosecuted, by many scientific men both at home and abroad. Many additions to our knowledge have thus been made; and the ultimate result will probably be, not only the adoption of new remedial agents and the abandonment of old ones, but the discovery of general therapeutical laws. When these have been discovered and formulated, therapeutics may claim to be ranked as one of the sciences.

Therapeutics does not mean simply the physiological actions of drugs and of other remedial agents on the healthy body, but their actions in diseased conditions. This affirmation appears self-evident, yet it is often forgotten; and the assumption is made that the action observed by the practical therapist in the hospital-ward will be the same as that described by the physiological investigator in the laboratory. In many cases, it is well known not to be so; and illustrations of this will be given in subsequent papers. It is necessary, therefore, if we wish to establish a rational system of therapeutics, not only to observe and describe the physiological actions of drugs on healthy animals, but also to notice these on animals in a morbid condition. This opens up an extensive field of research—namely, experimental pathology, a department of scientific work now engaging the attention of eminent pathologists, chiefly in Germany. There can be no doubt that, just as anatomy became exact by the use of the scalpel and forceps, physiology and pathology will become exact by the employment of rigid experimental methods of research. The field of experimental pathology is almost entirely a new one. Up nearly to the present time, we have been accumulating facts regarding diseased organs seen in the pathological theatre after the disease had done its worst. These facts relate chiefly to the physical and chemical characteristics of the diseased organ after death. They are of great value; but, in obedience to the law of the human mind, which prompts to the investigation of the causes of phenomena, we must now go a step farther back. We wish to know the preliminary stages of those morbid actions which have produced histological changes, either complete or partial, of the organ, and consequent loss or perversion of function. This can only be gained by experimental inquiry on animals; as the general rule is, that the disease does not destroy life in the human subject during an early stage, and, consequently, there is no opportunity for *post mortem* examination at that stage. By the artificial production of diseased conditions, however, we may study the successive changes in the tissue or organ which lead to a permanently morbid condition. Thus, accurate knowledge will be obtained which will serve as a basis for a new series of experiments as to the actions of remedies. Given certain morbid conditions, artificially produced, how may these be modified by the physiological actions of active substances?

Labour in this direction cannot fail in being well recompensed by the accurate knowledge obtained. Thus, pathology would become a help to therapeutics. The arrangement or classification of the functions of the body for physiological purposes is already recognised as the basis for pathological inquiry; in like manner, well established facts in pathology constitute a basis for scientific therapeutics.

I do not forget, in making these remarks, that before we can found a rational system of therapeutics, we should, as far as possible, become acquainted with what has been called the natural history of disease. As an element in the inquiry, this has been ably put forward by Dr. Rogers, in his work on *The Present State of Therapeutics*.^{*} Many diseases undoubtedly tend towards recovery. The patient would ultimately become well without medicine. The medicine given may have helped towards recovery, or the reverse. Supposing it has helped towards recovery, the effect has been produced by two causes—(1) the tendency towards recovery without the assistance of remedies; (2) the effect of the remedy. It is not easy to say how much is due to the one, and how much to the other. But the remedy may be beneficial in two ways, although it may not materially change sequence in the natural progress of the disease: (1) it may relieve the sensation of pain; (2) it may save time. Few will deny that it is in the power of the skilful therapist to relieve pain; but the question of time cannot be so easily settled. It can only be settled by taking a disease which naturally tends to recovery: the average duration of the disease in a given number of cases not affected by remedies must be noted; next, the average duration of the disease in a given number of cases influenced by remedies must be noted; and, lastly, the average durations of the two sets of cases are to be compared. It is not easy to make such observations as these, even in hospital practice. In private practice it is impossible, because social factors come into play. Hence, we must resort, for assistance, to experimental therapeutics. Many, if not all, of the ailments "flesh is heir to", may be induced in the lower animals. These may be placed in almost exactly the conditions we desire; and, consequently, we may be able to institute such comparative researches as will be of the highest benefit to the human race.

Before entering upon the question of the relation of chemistry to therapeutics, the preliminary questions of the relation of chemistry to physiology and pathology must be briefly discussed. Much of what is termed physiological or pathological chemistry is simply the chemistry of substances derived from the dead tissues. When a living tissue is subjected to certain chemical manipulations, it dies, and substances may then be found, such as albumin, globulin, gluten, etc., having specific chemical properties, and which are assumed to have existed in the tissue during life. Of the chemical composition and reactions of living matter, as was long ago pointed out by Fletcher, we know nothing positively; we are acquainted, however, to a limited extent, with the chemical properties of the plasma from which the living matter derives its nourishment, and of the fluids which contain the materials derived from the retrograde metamorphosis or degradation of the living matter after it has performed its functions. Of the exact chemical changes which occur when the living tissues take up nutrient matter from the plasma, we know comparatively little; nor have the successive steps by which living matter passes into dead matter been fully described. But while we may not know these processes with scientific accuracy, it is a great step to be able to analyse the nutrient plasma before it has been subjected to the selective action of the living tissues, and also to examine the chemical nature of those substances obtained from the disintegration of living tissues. By varying the chemical composition of the nutrient fluid, we can vary the amount and character of the retrograde substances. Thus, a large amount of nitrogenous material in the plasma is followed by a large amount of nitrogenous materials excreted. This has been shown by the experiments of Lehmann, Fick and Wislicenus, Parkes, Pavy, and Mahomed. Similarly, the chemical composition of the nutrient fluid affects the condition of the living tissue both statically and dynamically. Thus, a large amount of oxygen in the plasma circulating through a muscle causes it, according to Brown-Sequard and others, to perform more work and to increase in bulk. It is evident, therefore, that the chemical composition of the nutrient fluid affects both the activity and the growth of the tissue itself and the character of the excrementitious products. This fundamental and apparently self-evident truth will be better realised by viewing the living elements of body as proximately obtained from the internal medium or plasma. This plasma Claude Bernard calls the "physiological medium", because materials introduced as food must be converted into it before they can become a constituent of the tissues.

^{*} *On the Present State of Therapeutics, with some Suggestions for placing it on a more Scientific Basis.* By James Rogers, M.D., formerly Physician to the British Legation and to the Abouchoff Hospital at St. Petersburg. London: John Churchill and Sons. 1870.

Each tissue derives its nourishment from the plasma, molecule by molecule. Bathed in this fluid, the cellular elements of the tissues are, as Bernard says, "veritable aquatic organisms". The internal medium is incessantly fluctuating. Materials are constantly absorbed from without, and are there elaborated and made fit for assimilation. Materials are also constantly thrown into it as products of waste of tissue, and have to be excreted.

Modern scientific investigation has also shown that chemical changes not only occur in the living tissues which lead to their being split up into simpler chemical compounds, but also that certain elements of the food never become truly organised, or incorporated with the tissues, but undergo retrogressive chemical changes, which have an important part to play with reference to the production of heat and mechanical power. As examples of this kind of change, we may take the splitting up of albumin into a nitrogenous portion to be excreted, and into a non-nitrogenous residue, which, by oxidation of its constituents, carbon and hydrogen, produces energy; or the oxidation of fat, or of the carbohydrates (starch, sugar), or of alcohol. It is evident that the due performance of these chemical changes are essential to the health and capacity for work of the individual. It becomes a matter of inquiry how far these processes are affected by morbid conditions, and how far they may be influenced by the actions of remedies.

In this department of physiology, the question is ever present to the mind—how far the vital phenomena of nutrition may be explained by the laws of chemical combination? These phenomena may simply be the results of chemical combination occurring under special conditions of structure, etc.; but of this there is no proof. The phenomena of nutrition differ so widely from mere chemical phenomena, that they must be due to widely different conditions. "We may never know all these conditions; but that analysis will ever resolve them into simple chemical conditions, irrespective of the speciality of their theatre, may confidently be denied."—(*Problems of Life and Mind*. Lewis, vol. i, p. 113.)

The chemistry of nutrition is specially alluded to here, because it appears to me that, when we are better acquainted with it, we will be in a better position to understand the physiological actions of certain remedial agents.

Changes in physiological activity must be produced either by the direct action of substances on the tissue or tissues affected, or by action on the plasma, or elements of the plasma, which nourish the tissues. How are these tissues affected? If the nutritive plasma which supplies them, in normal circumstances, with the materials they require, be affected chemically by the introduction of a new substance (say a substance called a poison), it is evident that the relation between the plasma and the living tissues will be altered. We do not know, in the present state of science, what this alteration may be, or how it is effected. It is possible that, in some cases, the poison may become incorporated with the living matter before it is capable of affecting its vital action. In other cases, the so-called poison may not become part of the tissue, but may interfere chemically with the changes continually taking place between the tissue and the plasma surrounding it. At present much of this is mere conjecture. The field of histo-chemistry with reference to therapeutics requires to be further cultivated, and it appears to me, that the line in which this is to be done, is by observations on the reactions of minute quantities of chemical substances on living lower organisms, such as *Monera*, *Amoeba*, *Paramecium*, and other infusoria; and also on the colourless cells of the blood and other masses of bioplasm found in the body. By pursuing this path of work, it is probable we will learn much regarding the actions of drugs on the ultimate living textures which are concerned in nutrition, innervation, and reproduction.

The conclusion at which we arrive is, that we know little regarding the chemical processes occurring in the living body, either in health or in disease, which can be of much service in the practice of therapeutics. But we know that chemical processes do occur which are closely connected with the manifestation of vital phenomena. If such chemical changes do occur, we may reasonably expect to be able to influence them by the introduction of chemically active substances. This opens up another line of inquiry; namely, how far can we produce changes in physiological action by changing the chemical composition of the substance introduced into the body? The answer to this question is not only likely to be of practical service to therapeutics, but it may reflect light on the true character of those chemical changes occurring in the living tissues, the investigation of which is so difficult.

A SUGGESTIVE INCIDENT WHICH OCCURRED DURING ETHERISATION.

By FURNEAUX JORDAN, F.R.C.S.,

Surgeon to the Queen's Hospital, and Professor of Surgery at the Queen's College, etc.

EVERY surgeon, it may be presumed, desires to use the safest and most effectual anæsthetic. Those who prefer chloroform believe that, in expert hands, it is safe, and has fewer drawbacks than ether. Conceding much on this point, we must not forget that, while narcotisation is everywhere a daily, an almost hourly, need, its induction does not always fall into experienced hands. If, then, anæsthetics must be frequently administered, and administered with variable degrees of judgment and experience, a growing amount of evidence points to ether as the safer anæsthetic.

Recently, I was about to place a ligature on the femoral artery for popliteal aneurism. The patient having been etherised by my colleague Mr. Priestley Smith, who is very familiar with the use of ether, I made the usual incision in the integuments. The patient showed no sign of pain; but I had scarcely completed the incision, when the limb was seized with a marked tremor of the muscles. To clean a large artery with a sharp knife (and I believe, with the late Mr. Syme, that to dissect an artery with a sharp knife is less mischievous than to contuse it with blunt instruments) in a violently trembling limb is not a desirable proceeding. At my desire, more ether was given, but the tremor continued unabated. I again desired that more ether should be given. Mr. Priestley Smith's immediate and significant reply was this: "The man is as much under the influence of ether as it is possible to put him." With the assistance of firm pressure on the muscles of the thigh, I completed the operation; and I may add, that the man has (fourteenth day) done perfectly well.

From the incident just related, a few useful conclusions may be drawn. The most important is this: the profoundest anæsthesia of ether is not so deep as to prevent reflex muscular tremor from following an incision in the skin. It is probably much less profound than even ordinary degrees of chloroform-narcotism. In short, it would seem that, with common care, a patient cannot be put dangerously under the influence of ether. Nevertheless, the anæsthesia of ether is sufficient for the vast majority of operations. Ether, then, notwithstanding certain drawbacks, should claim our first attention.

The chief drawback of ether is, that it cannot be readily administered by timid persons. Anybody can pour a little chloroform on to a handkerchief, and hold it over a face. Not everybody can resolutely pour out a large quantity of ether, resolutely and closely bind a towel round the mouth and nose, and resolutely disregard the most violent muscular contortions. But these are difficulties which very attainable knowledge and experience will surmount.

In a few operations where the skin needs to be freely incised, and especially where such incisions precede delicate and anxious manipulations, the deeper influence of chloroform may be desirable. Quite recently, the practice of beginning with a little chloroform, and then giving ether, answered extremely well in the hands of my colleague Dr. Sawyer in the case of an old man, from whose tarsus I removed a carious patch by means of a large trephine, after a free crucial incision in an "Esmarchised" limb.

In this note, it is far from my intention to discuss the general question of anæsthesia; but a few words, and a few only, on chloroform. I entirely coincide in the opinion, that every kind of "apparatus"—everything containing "valves"—should be scrupulously avoided. Every effort should be made to prevent, what so readily occurs, a deeper anæsthesia than the particular operation, or stage of operation, requires. Timid chloroformisation is, especially in the early stages, equally mischievous. Timidity in the administration of chloroform means much more chloroform, longer time, and greater danger. Again: conjunctival insensibility is too rough a test; it may come too soon. Much worse, it may come too late. In children, the conjunctiva is often insensible in a few moments, especially if there be anything on the stomach. As regards food in the stomach, in hospital practice it is common for mothers, when they are instructed to bring children without breakfast (or other meal) to give them some outrageous compound—beer and fruit, apples and pears, being the commonest—under the impression that these are not a meal, and that the poor child must be "strengthened" for the operation. Occasionally, as in old imbibers, the skin is ready for the knife before the eye tolerates the finger. The deep pinch of an artery-forceps at the seat of the operation is a better test.

Donations.—Mr. Daniel Thwaites, J.P., has forwarded a cheque for the sum of £424 to the secretary of the Blackburn and East Lancashire Infirmary, which clears off the debt upon the institution.

DIPHTHERITIC PARALYSIS:

ITS NATURAL COURSE, PATHOLOGY, TREATMENT, AND RELATION TO PARALYTIC AFFECTIONS FOLLOWING FEVERS.*

By SIR JOHN ROSE CORMACK,

Chevalier of the Legion of Honour; M.D. Edin. and Paris; F.R.S.E.; Fellow of the Royal Colleges of Physicians of London and Edinburgh; Physician to the Hertford British Hospital, Paris; etc.

[Continued from page 106.]

THE following case is one of the most interesting of those of the class to which it belongs, which I have been able to watch minutely throughout the whole of the primary and secondary symptoms. To be rightly appreciated, it must be studied in all its details, and viewed in conjunction with other cases apparently but not really different from it in their pathology.

CASE.—Alice B., an English girl, aged 21, nursery-maid in an English family residing at Passy, Paris, was admitted to the Hertford British Hospital on September 30th, 1874. She had then been only one month resident in France. For the three days immediately preceding her admission, she had been under treatment by a French physician, who intimated that she was suffering from a *fièvre muqueuse*, likely to be of considerable duration and severity. Under these circumstances, I was requested to receive Alice B. into the hospital.

The following is a summary of the history of the case from its commencement up to the time of my reception of the patient. For ten days, she had felt weak and not up to her work; but till Saturday, September 26th, she did not state, or perhaps did not realise, that she was really ill. On that day, she complained of severe pain in the back, and repeatedly had trembling fits. Her mistress, who accompanied her to the hospital on the morning of Wednesday, September 30th, when I received her, informed me that the patient did her work on the 26th, making no complaint of being unwell. On that day, however, her manner was observed to be peculiar. On the evening of the following day (Sunday, September 27th), she became delirious. Against her inclination, she was sent early to bed on that evening, where she remained under medical treatment till her removal to the hospital on the morning of Wednesday, September 30th. When she arrived, I was engaged in making the ordinary visit. As soon as she was undressed and somewhat rested, I proceeded to examine her.

September 30th, 1874, on admission. Her face is slightly flushed. Her expression is vacant and bewildered. The pupils are equally and much dilated. The respiration is oppressed. "Breathing tires me," she says. The pulse is 100, feeble; the temperature is 40.1 C. (104.18 Fahr.) The tongue is moist, clean at the tip and edges; in its centre, there is a loose white fur. The bowels were much moved early this morning, soon after a dose of castor-oil. Some urine, passed an hour after admission, was found, on being tested by heat and nitric acid, to be slightly albuminous. The abdomen is moderately distended; it is nowhere tender on pressure. No gurgling can be detected in the right iliac fossa. There is no acute delirium, such as she is reported to have had on Sunday night. When first spoken to, her replies are hesitating, confused, and contradictory; when thoroughly roused, they become coherent; but, if questioned too long, she relapsed into bewilderment. No medicines are prescribed. She is ordered to have the usual nutritious liquid diet of our fever-patients, consisting chiefly of milk, beef-tea, and farinaceous substances, the former greatly predominating. The maximum allowance of stimulants, till further orders, is fixed at twelve ounces of claret in the twenty-four hours. As a common drink to allay thirst, she is ordered barley-water acidulated with lemon-juice.

October 1st, 11 A.M. The countenance is more natural than it was yesterday. Her mental state is very similar. She had no sleep from the time of her admission till six this morning, when she fell asleep, and slept quietly for nearly two hours. She now complains of insomnia, and begs for medicine to induce sleep. The urine, still slightly albuminous, is pale, and passed in large quantity. There is some diarrhoea, but no increase of abdominal distension or tenderness. The pulse is 100 and feeble. The temperature about eight this morning was 39.8 C. (103.6 Fahr.); the pupils are dilated as yesterday. There is no eruption on any part of the body.—5 P.M. Seven very characteristic rosy lenticular spots are visible on the chest, which disappear on pressure and reappear when the pressure is removed. She complains of being weary from want of sleep, but does not seem restless or in bodily discomfort. She is ordered to have, at 10 P.M., a starch-enema containing twenty-five drops of the *British Pharmacopœia*

solution of the hydrochlorate of morphia.—8 P.M. The temperature is 40.8 cent. (105.44 Fahr.)

October 2nd, 11 A.M. Her appearance is very much the same as it was yesterday; perhaps there is more hebetude. She had several short sleeps of from five to ten minutes several times during the night. Since admission, no active delirium has been observed. There is no tympanitic distension, and very little tenderness of the abdomen. Since 5 P.M. yesterday, a few more rosy lenticular spots have appeared; they are situated on the back and arms. When there is a long interval between the doses of wine, the breathing always becomes oppressed; she asks eagerly for wine. The full allowance of twelve ounces of the best claret in the twenty-four hours is being taken. She takes willingly a sufficient quantity of beef-tea and milk.—8 A.M. The pulse is 120, and the temperature is 39.8 C. (103.6 Fahr.) The diet and wine are to be continued as at present. She is to have a starch-enema containing twenty-five drops of laudanum every night at 10 P.M. till further orders.—6 P.M. The pulse is 116, and the temperature 40.8. No more spots have appeared.

October 3rd, 11 A.M. Her general appearance is very similar to that which it presented yesterday. Though she has had very little sleep, she has remained tolerably quiet since having the morphiaed starch-enema. Once only during the night—for about half an hour—she was restless and delirious. She then several times addressed by name the children of whom she had charge before admission, rising up in bed and screaming to them, to warn them of some impending danger. No more fever-spots have appeared. At 8 A.M., the temperature was 40.2 cent. (104.36 Fahr.), and the pulse 116. At present, the pulse is 120.—8 P.M. There has been low muttering delirium during the day. The temperature is now 40.3 C. (104.54 Fahr.), and the pulse 120.

October 4th, 11 A.M. The wine and diet have been continued as prescribed. The morphiaed enema was not administered last night. She is at present free from delirium and is calm. During the night, however, she was very delirious, twice tried to get out of bed, struck the nurse several times, and made many complaints of being cruelly treated, particularly of being placed on a bed of rotten potatoes. In the early dawn, when she had been quiet for some time and was apparently emerging from a slumber, she was asked by the nurse if she felt better. Her reply was, "I am very weary; for, till I lay down here, I had been walking about the streets of Paris all night, seeking for, and unable to find, the hospital." She had a somewhat loose motion early this morning; but neither now nor since admission to the hospital has the looseness amounted to diarrhoea. About 8 A.M., the temperature was 39.7 cent. (106.43 Fahr.), and the pulse 116.—4 P.M. She is very excited, and has been so since she received a visit from her late mistress at 2 P.M. The respirations are 36; the pulse is 124; and the temperature 40 cent. (104 Fahr.). There is an icteric tint of the eyes and of the skin all over the body. The urine since yesterday has assumed a very dark colour, and to-day is quite like the urine of jaundice. She is reported to have had increased excitement immediately after the last two or three doses of wine. Orders are given to diminish the wine one-half, if it seem to induce excitement. An enema containing twenty-five drops of the *British Pharmacopœia* solution of the hydrochlorate of morphia has now been administered, and another similar enema is ordered to be given at midnight.

October 7th, 11 A.M. Since Sunday (the 4th), she has been restless, almost sleepless, and in a state of active delirium. She is at present delirious. She is now calling out to absent persons as if they were present, and manifesting a delirious loquacity very like that which is common in delirium tremens. The lower half of the left lung is dull on percussion, and in the same situation the breath-sound can scarcely be heard on auscultation. The respiration is short and shallow; and occasionally, for a few minutes at intervals, she has a paroxysm of very hurried breathing. From her extreme restlessness, jactitation, and subsultus tendinum, it is impossible to take the pulse, respiration, or temperature. There is slight abdominal tenderness on pressure, and a moderate amount of tympanitic distension. The urine and feces are passed unconsciously. The urine—judging from the wetness of the napkins placed under her—is not scanty. The alvine evacuations are copious, black, and loose, but not watery. Her countenance has a wild and restless expression. Her pupils, which, since her admission, have been very dilated, are now more dilated than they have yet been, and are irresponsive to light. Her voice, like that of an inebriated person, is thick, and, at times, almost inarticulate. Since yesterday her wine has been increased to a *litron*, and to her hourly dose of wine two or three teaspoonfuls of brandy are occasionally added; the maximum quantity of brandy to be given in the twelve hours being three ounces. Immediately after taking a brandied dose of wine, she moved her tongue better, spoke much more clearly, and became less agitated. I asked her how she felt; when she at once replied:

* Partly read before the Medical Section at the Annual Meeting of the British Medical Association in Norwich, August 1874.

"Quite well—are the boxes packed?" Several times since this report was commenced, she has exclaimed: "Are the children all right?—Who are with the children?" Those questions are evidently suggested by the fretful cries of an infant in an adjoining ward. Her eyes are expressionless and never closed. She seems to see objects imperfectly, for she cannot tell me whether a chair near her bed is a chair or a table. She at times addresses the nurses as "nurses" and at other times names them by the names of persons who are in England. At present, and occasionally at intervals, her delirium is characterised by loquacity and excitement. The lady-superintendent and nurses concur in stating that during the last three days there has been a well marked periodicity in the maximum of her excitement, and that this has occurred twice in the twenty-four hours, viz., between 4 and 5 A.M. and 4 and 5 P.M. She is ordered to have, at 3 P.M., an enema, consisting of twenty-five drops of the solution of the hydrochlorate of morphia of the *British Pharmacopœia*, four drachms of spirit of turpentine and one ounce of camphor water.—5 P.M. She is much quieter, a noteworthy fact, for lately the maximum excitement and jactitation have occurred very regularly at this hour. There is no increase in the abdominal tenderness. She is now in a profuse perspiration. Since the morning visit, she has passed unconsciously a consistent stool and some urine. She takes her wine with avidity, but now it is only almost by compulsion, that she swallows milk or beef-tea. The milk, beef-tea, arrow-root, wine, and brandy are to be continued as at present. Another enema similar to that given at 3 P.M. is to be administered at 10 P.M.

October 8th, 10 A.M. The instructions of yesterday have been carried out in every particular. She slept very little during the night. The countenance has improved. She is now lying on her back with her eyes closed, but not asleep. When asked to open her eyes, she makes a visible unsuccessful effort to obey. She is placed from time to time on her side, but at once reverts to the dorsal decubitus, unless so propped as to render this impossible. There is no jactitation. The subcutis tendinum in both arms is incessant. Elsewhere at present there is neither subcutis tendinum nor muscular twitchings. At eight this morning, her pulse was 120 and her temperature 39.5 C. (103.1 Fahr.)—10 A.M. The pulse is 120. The respiration is unequal in depth, and varies from 30 to 34 in the minute. When told to open her eyes and put out her tongue, she does both to the best of her ability, but very imperfectly. The eyelids separate slightly, and the tip of the tongue is shown at the half-open mouth. The pupils are still much dilated, but to a less extent than yesterday; they are sensible to light. The tongue and lips are parched and covered with black sordes. The speech is shaky, hesitating, slow, thick, and difficult to understand, much as it was yesterday. Since noon yesterday, she has had no stool. She continues to pass urine unconsciously; it does not appear to be scanty, but, being passed in napkins, it is impossible to estimate its quantity. From 11 o'clock last night till 7 this morning, she perspired profusely; the skin is still very moist. There is some loose cough, but no expectoration. The crepitant *râles* in the lower third of the left lung are much louder and coarser than they were yesterday; they are chiefly heard behind. Whilst this report was nearly finished, the patient, immediately after a brandied dose of claret, slowly opened her eyes, and said, "Am I better?" She had evidently been attending to the record which was being made of her symptoms. When I replied "Much better," she smiled intelligently. This incident is specially noteworthy. Several physicians who have been present when I have interrogated this patient have supposed that, when I got no replies, she was in a state of imperfect consciousness; whereas her not putting out her tongue when told, and not replying, has arisen from want of muscular power. To-day, till she had her wine twice, she could neither speak nor show her tongue. Two tablespoonfuls of castor-oil are to be immediately administered. The brandy is stopped, and in its place four ounces of rum are to be given in the twenty-four hours in milk. The wine and aliment are to be continued as at present, and the morphiated enema is to be repeated at 3 P.M.

October 10th, 10 A.M. Her condition yesterday was very much the same as on the previous day. The bowels were relieved early yesterday morning by an enema of tepid water some hours after the administration of the castor-oil. The treatment ordered on the 8th has been continued till this time. Since last report, she has been gradually becoming less restless, and has several times given indications that she was interested in what was passing in the ward. She has been perspiring so profusely as to require several changes of linen in the twenty-four hours. The countenance is more intelligent, and her expression, when spoken to, shows that she understands what is being said to her. Superficial examination might lead to an opposite conclusion; for she does not reply when spoken to, and, when asked to put out her tongue, she makes no other sign of attempted compliance than a slight separation of the lips, accompanied by an earnest gaze

which clearly declares, "I would if I could". She lies on her back, moving neither upper nor lower extremities, as if she were paralytic. There is some difficulty in swallowing. Faeces and urine are passed involuntarily. There is no jactitation. There is subcutis tendinum in both arms, which is always at its maximum before, and at its minimum soon after, she has had a dose of stimulants. The pulse is 124, and very feeble. The treatment is to be continued.—8 P.M. The pulse is 116, and still very feeble. In the morning, at 8, the temperature was 37.9 C. (100.22 Fahr.); it is now 38.8 C. (101.84 Fahr.)

October 11th, 10 A.M. She passed a good night. A great change for the better has taken place in her appearance. Her countenance has nearly lost the remains of vacancy which still existed yesterday. She can somewhat protrude the tongue in obedience to orders; and can answer with perfect intelligence—in one, two, or three cautiously enunciated words—the questions I put to her regarding her symptoms. The skin is very moist. At intervals, she has paroxysms of sweating so profuse as to drench her personal linen and soak the sheets of the bed. Yesterday, she seemed to have no voluntary power of movement in the limbs. To-day, she slightly moved her arms and legs when urged to do so; but, after having repeated this performance by my request, three or four times in quick succession, the motor power was gone. She does not seem to experience any difficulty in swallowing.—8 P.M. When raised for a minute or two, about an hour ago, to a semirecumbent position, she nearly fainted. Up to that time, she had seemed stronger, and had been able, when requested, to flex, to a certain extent, her arms and legs. At 8 this morning, the pulse was 126, and the temperature 37 C. (98.6 Fahr.); at present, the pulse is 100, and the temperature 37.4 C. (99.3 Fahr.) The pulse is exceedingly feeble. The instructions now in force in respect of treatment are renewed, with this addition—that, without being raised from the horizontal position, she is, from time to time, to be placed alternately on either side; and that, in the event of a threatening of faintness, she is at once to have one or two tablespoonfuls of port wine.

October 12th, 11 A.M. She had port wine several times during the night in consequence of her exceedingly exhausted state on awaking at intervals from sound sleep. She continues to perspire very freely, but the perspirations are not to-day of a drenching character. The tongue is cleaning. The state of the abdomen is normal. The urine and faeces are generally, but not always, passed involuntarily. The countenance is flushed. She takes large quantities of beef-tea thickened with tapioca or arrowroot, and at the rate of a *litre* of milk daily. Notwithstanding this alimentation, she is exceedingly dependent upon the free use of alcoholic stimulants. Were they not given in abundance, and at the exactly required time, she would certainly die from failure of the feeble heart. On the 8th, 9th, 10th, and 11th, she had, each day, thirty-six ounces of strong claret, four ounces of rum, and six ounces of port wine. The instructions now in force are renewed, with this reservation—that the quantity of stimulants is to be reduced should headache or flushing supervene.

October 13th, noon.—During the last twenty-four hours, she has had a large quantity of beef-tea and milk. During the same period she has had also thirty-six ounces of claret, but no other stimulant. She is weak, exceedingly drowsy, and remains in a state of considerable perspiration. Her pulse is 64, and her temperature 37.7 C. (99.86 Fahr.) Occasionally, she has a little loose cough. The respiration is slow and weak, but she does not seem to experience any discomfort in breathing. The tongue is moist: it is clean except towards the root, where it is slightly coated with a brownish fur. There is neither tenderness nor distension of the abdomen. She has had no stool since the evening of the 11th. For some days past she has shown so great an aversion to beef-tea, that she has taken much less of it; but to compensate for this, her allowance of milk has been greatly increased. During the last twenty-four hours she has drunk very nearly two *litres* of milk. Early every morning and afternoon she is to have an egg-flip, containing in each an ounce of brandy. During the twenty-four hours, she is to have one or two small custards. Add to the beef-tea, in addition to the tapioca or arrowroot, two or three tablespoonfuls of a *purée* of mixed vegetables—viz., carrot, turnip, and Brussels sprouts. She is to have immediately a draught containing three drachms of (*British Pharmacopœia*) compound tincture of rhubarb, five grains of carbonate of ammonia, and an ounce-and-a-half of camphor-water, to be followed in three or four hours by an enema of tepid water, if the bowels have then not been moved.

October 14th, noon.—Yesterday the bowels were freely moved, after the rhubarb draught and enema had been administered as directed. If there be any change since yesterday in her condition, it is for the better. She takes her food well in accordance with yesterday's programme. The treatment in respect to food and stimulants is to be continued.

October 15th, noon.—During the early part of the night she slept

well, but towards morning became wakeful, very hot in the head, and flushed in the face. These symptoms were relieved by the diligent application of cold water to the head. She is certainly in a less favourable state than when reported at noon yesterday. The aphasia is nearly complete. During the night and early morning she complained, in thick and difficultly understood speech, of severe pains in the arms and legs. The bowels have not been moved since the enema. The treatment to be continued in respect to food and stimulants so long as they are taken willingly, and without causing increase of flushing or excitement.—4.30 P.M. The nurse reports that she has been yawning and sighing incessantly for the last three hours; she is doing so at present. There is cutaneous anæsthesia, and severe shooting muscular pains in the left leg, in which the motor power is less than in the right leg. In both lower extremities the power of voluntary movement is small, and is soon exhausted by being exerted. She feebly squeezed the hand with her right, and also with her left hand when told to squeeze; but on her repeating the squeezing several times in succession, it was found that the amount of pressure went on diminishing, till at last it was not appreciable. When asked to show her tongue, she partially protruded it; but, after protruding it several times, she lost the power to do so. That she did her best, was evident from her separating the lips and pushing the tip of her tongue against the teeth.

October 16th, 11 A.M. The night-nurse reports that during the greater part of the night there was considerable restlessness and stertorous breathing. Between 7 and 8 A.M., when seen by Mr. Baillie Cormack, the patient was not restless, but was breathing stertorously. Her pupils are exceedingly dilated—much more dilated than I have yet seen them. There is complete aphasia. When asked if she had headache, she put her right hand to her head, and looked at me, as if she meant thereby to answer in the affirmative. This she did three times, looking earnestly at me at the same time, as if she would fain explain herself in words if she could. Her expression was that of perfect but anxious intelligence. She continues to pass her urine and feces in bed; both are voided involuntarily, but not always unconsciously. About seven o'clock this morning, the nurse, when removing the soiled napkins from under her, observed that there was complete paralysis of the left arm and leg. At that time, the nurse assures me that neither leg was swollen, but that, two hours later, the right leg began to swell. It is now quite cold, has a glistening appearance, is very much swollen as high up as the knee. It does not pit much on pressure. On examination, I find that the patient is hemiplegic. The left leg is absolutely palsied; the right leg, on the other hand, is more under the influence of volition than either has been for some days. On tickling the sole of the left foot, it is energetically drawn up; and, on the tickling being continued, the leg is almost convulsed. The right—the non-palsied leg—is very much less influenced by tickling the sole of the foot. Although the non-palsied lower extremity is responsive to the will of the patient, its motor power is very soon diminished, and is at last exhausted by continued use. In both lower extremities, there is increased cutaneous and deep-seated sensibility, as is proved by a cry indicative of pain and a wincing of the features immediately following slight or firm pressure. The pulse is 128, and the temperature is 38°C. (100.4 Fahr.). The bowels are confined; the tongue is foul and dry. She is to have a saline-purgative enema. The lower extremities are to be swathed in several folds of cotton wadding, and then packed up in warm flannels. India-rubber bags filled with warm water are to be kept close to the limbs, so as to maintain a warm equal temperature. Cold water is to be kept diligently applied to the head so long as its use continues to be, as it now is, soothing and agreeable to the patient. The wine is to be given very moderately so long as the heat of head and flushing of the face continue. She is to have milk and water as an ordinary drink; and milk-diet and beef-tea as hitherto, except that the quantity of beef-tea is to be diminished so long as the heat of head and present high temperature exist. A cradle is to be placed over the legs, to bear the weight of the bedding.

October 17th, 11 A.M. The night-nurse reports that during the night the patient, on awaking from sleep and having a dose of wine, made several great efforts to speak, and succeeded to some extent, with thick voice and active eye, to express that she was suffering great pain in both legs. At 8 A.M., the pulse was 120, and the temperature 38.1°C. (100.6 Fahr.). At present, the pulse is 110. The head is cool, and the countenance tranquil. The tongue is rather moist. The skin is dry, but not hot. The right—the non-palsied leg—has no longer a glistening appearance, and is now hardly at all swollen. The left—the palsied leg—has become very much swollen, as much swollen as was the right leg yesterday. There is no increase in the sensibility of its general cutaneous surface; but slight pressure, made in the course of both the internal and external saphena veins, causes the patient to move the limb with almost spasmodic energy, and to give evidence by the wincing of

her features that great pain is being caused. The veins are invisible, from their deep-seated adipose position and the swollen state of the limb. Manipulation gives so much pain, that their state cannot be determined satisfactorily by tactile examination; but the touch nevertheless gives an impression that cord-like bodies exist in the course of the veins. By the exercise of voluntary power, the patient cannot move in the smallest degree the left upper or lower extremities. The mouth is drawn to the right side; but this is only slightly apparent when the countenance is in a state of repose, though strikingly visible when she smiles, which she has done repeatedly since this report was commenced. When asked to show her tongue, she protrudes it very slowly, very carefully, and with an air of deliberation, just as if she were performing an operation requiring adroitness and meety of calculation. The tongue, however, is fully protruded. After she had exercised some minutes in protruding the tongue, its protrusion became increasingly difficult, and was at last temporarily extinguished. There is less aphasia. She has to-day a peculiarity of speech which I have not before observed. Her voice is still so thick that it is very difficult to recognise the words she employs; but she has a new peculiarity—the words are as it were thrown out of her mouth by a concentrated effort or jerk. Her intelligence is perfect. She asked and answered questions regarding her paralysed state and her general condition in a correct discriminating manner, though much distressed by the physical impediment to speech. Her three principal complaints are, that she can hardly speak; that she has pain in a situation she indicates—viz., in the course of the left internal and external saphena veins; and that she is now stunted in her wine, without which she cannot utter words. She has some difficulty of breathing, but it is neither an urgent nor a constant symptom. The breath-sound is feeble posteriorly in both lungs, but is feebler in the lower third of the left lung than in any other situation. The alvine and renal evacuations are natural. The dingy yellow hue of the skin is disappearing. Let a large blister be applied to the front of the chest, and treated with poultice, cotton-wadding, and linimentum calcis.—8 P.M. Visiting another patient, I casually asked her how she felt. I am struck by the improved voice in which she has replied "Much better". Her countenance is cheerful and natural. She had just taken a tumbler of milk containing an ounce of rum. On telling her to flex the forearm on the arm of the palsied extremity, I saw the biceps feebly but distinctly contract, the result of which was a corresponding slight flexion of the forearm. On a second trial, a similar result was obtained. A third and a fourth trial proved complete failures.

October 18th, 2 P.M. She passed an excellent night. The countenance is very cheerful. The oppression in breathing seems nearly gone. The blister rose well, and has discharged an abundant serosity. The blistered surface is now covered with layers of wadding in the usual way. She remarked that she liked the blister, and hoped that she would soon have another. There is no swelling of the right leg. The left—the paralysed leg—is much less swollen than yesterday; it is still painful on pressure in the course of the saphena veins. No indurated cords can be made out, but nevertheless it is possible that they exist. The pupils, though still very much dilated, are less dilated than I have observed them since the hemiplegic attack. The skin is very moist, but for some days there have been no profuse perspirations. The dingy yellowness lately so apparent on the face, neck, and arms, is less to-day than it has been for a week. There is no longer any yellowness of the conjunctivæ. She can converse fairly well for two or three minutes, after which her speech becomes thick and embarrassed, and at last fails.

October 31st, 11 A.M. Since the 18th, there has been a steady daily improvement. To-day, she is sitting up for the first time. She can speak for a few minutes without being fatigued. The face, however, betrays the paralytic affection. She can, by leaning on a chair and pushing it before her, move about a little, dragging the left leg. She has regained very little squeezing power in the left hand, but in this respect for some days past there has been decided amendment. Since the 25th, she has taken with her principal meal—ordinary hospital fare of soup, meat, and vegetables—a pill containing one grain of the extract of *nux vomica*, one grain of the saccharine carbonate of iron, and two grains of the compound rhubarb pill. She has likewise had every morning an enema of tepid water, by which means a satisfactory state of the bowels has generally been maintained. There is now a greater tendency to constipation. Her allowance of stimulants has for the last few days been one *libre* of claret in the twenty-four hours, and one ounce of rum. The latter is taken in a tumbler of milk when the morning movement of cleaning begins in the ward about seven o'clock. She is not now fed during the night, as she sleeps soundly without awaking.

November 1st. She is progressing favourably. She is allowed to

sit up some hours daily. She is to take one of the pills prescribed on the 25th after each of the two principal meals; and, when necessary, she is to have a tumbler of Pullna water as an aperient.

November 5th, 11 A.M. Since November 1st till yesterday, her condition in respect of the hemiplegia has remained stationary. Her general state has been less satisfactory; but till yesterday, except occasional complaints of frontal headache, there has been nothing in her symptoms to attract particular notice. She awoke yesterday morning with severe headache, flushed face, and dry tongue; and has not since been able to sit up for a short time, as she had been doing daily. Her relapse is probably the result of over-eating and having had more than enough wine. Prior to the 1st, she had for some days been quite ravenous for food. For wine, her craving was also inordinate. To satisfy these desires, she had been supplementing her own very abundant alimentation by using secretly wine and meat which other patients gave her from their superabundance. Her pulse is 120, and her temperature 39.0 cent. The urine is rather scanty. The bowels are confined. She has no appetite. She is to return to a liquid diet, to discontinue the pills, and to have forthwith a tumbler of Pullna water. Till the headache and heat of head cease, cold water is to be diligently applied to the head.

November 9th, 11 A.M. Both symptoms and treatment have continued very much as reported on the 5th instant till this morning, when some amendment in her state is observed. There is a slightly increased power both in the arm and leg. The headache continues, but is rendered bearable by the diligent application of cold water to the entire head. She still sleeps badly, but she slept better last night than for some previous nights. The bowels are moved once or twice daily—sometimes without, and sometimes with, the aid of Pullna water and an enema. The tongue is cleaning. The respiration is natural. The skin is soft, but not moist. The pulse is 104, very compressible; the temperature is 37 C. (98.6 Fahr.). She refuses her food, but takes wine greedily. A very careful examination of her state has now been made. The veins are rendered invisible by the swollen state of the limb and their deep-seated subadipose position. Digital examination occasions so much pain, that it cannot be satisfactorily employed to determine their condition; but it is nevertheless correct to state that the touch gives to a certain extent the impression of cord-like bodies existing in the course of the veins. There is not the slightest voluntary motor power in either the upper or the lower left extremity. The mouth is considerably drawn to the right side; this is much less apparent when the countenance is in a state of repose; it is very striking when she smiles, as she has often done during the preparation of this report. When asked to show her tongue, she protrudes it very slowly and with an air of thoughtfulness, as if she were performing an operation demanding the exercise of the greatest skill. The protruded tongue deviates to the right.

November 10th, 11 A.M. Since the 9th instant, there has been a distinct daily amendment in all the symptoms. To-day, she is ordered to have ordinary diet. The only addition to the ordinary allowance of food and wine is a continuance of the morning ounce of rum in a tumbler of milk. She sits up daily for an hour.

November 17th, 11 A.M. She is up and dressed. She looks well. The pupils are now very moderately dilated. The tongue is clean; the pulse is 70. She speaks without hesitation, and her articulation is distinct and perfect. She cannot, unless supported, take more than three or four steps; even when supported, her gait is very unsteady, and the left leg is slightly dragged. She says that she has not quite as much power in the left arm and hand as in the right; but she uses both arms apparently as well as other people, and the grasp with the left hand is not weaker in proportion to the grasp with the right hand than is usual.

December 1st. She is now quite well. Except a very slight weakness in the left leg, no trace of any paralytic symptoms remains. The rum and milk to be discontinued.

December 8th. No trace of the paralytic symptoms remains. She can walk up and down stairs. The catamenial discharge has returned in a normal manner after missing three periods.

December 16th. She has remained since the 8th free from any paralytic symptoms or local weakness of any kind. She leaves the hospital to-day, plump, and in excellent health.

On every occasion in which the temperature was taken in this case, the thermometer was introduced into the axilla. The cold affusion was frequently used in a modified form throughout the treatment, and generally with the result of abating restlessness, and sometimes of inducing sleep.

[To be continued.]

THE USE OF SULPHURIC ETHER AS AN ANÆSTHETIC.

By THOMAS KEITH, M.D., Surgeon for Ovarian Disease to the Royal Infirmary, Edinburgh.

I OUGHT ere now to have communicated to the JOURNAL my experience of sulphuric ether. I have given it in ovariectomy and other prolonged operations, or whenever it was necessary in feeble patients to give an anæsthetic, ever since the beginning of 1867, when I doubt if anyone used it in this country except myself.

In giving an account in the *Lancet*, August 1870, of my second series of fifty cases of ovariectomy, the following remarks were made.

"In Case LII, the excessive chloroform vomiting during the operation, and for some time after it, so prostrated the patient, that her chance of recovery was lost. In the early cases, I have frequently had to deplore the injurious effects of chloroform vomiting in ovariectomy, and so evident was the mischief occasioned by it in this unfortunate case, that I have since then entirely abandoned the use of this agent in ovariectomy and other severe and tedious operations, and now use instead anhydrous sulphuric ether, made from methylated alcohol, administered through Dr. Richardson's apparatus. The oftener ether has been given, the more I like it. How chloroform so quickly superseded it is a marvel. The anæsthesia of ether, though at first slower, is extremely steady and quiet. There is infinitely less vomiting than with chloroform, and, instead of the pallid face and feeble pulse of chloroform, the patient, after a long operation, is put to bed with a flushed face and a great surface-circulation. In cases of non-adherent tumour, vomiting is, I fancy, of little consequence; but, where there has been extensive adhesion, and when oozing may be set up by it after the wound is closed, vomiting can be no trifle, and may turn the scale. Sulphuric ether has now been used—at first with a small proportion of chloroform—in 53 cases of ovariectomy (of which 46 recovered), and something has been gained from the use of it. I would put in a word for the old anæsthetic. Chloroform certainly saves the surgeon five or ten minutes of time, and a little trouble. Had it never been heard of, I doubt if humanity would have suffered from the want of it."

This opinion was looked upon here as heretical, and, being adverse to chloroform, was attributed to personal motives; yet, after four years, I have little more to add than simply to endorse it.

The case above referred to was at the time published in the *Edinburgh Medical Journal*, and I felt so certain that chloroform vomiting killed the patient, that in the case which came next I took to sulphuric ether in a sort of despair. It was not new to me, for in 1847-48 we all looked upon ether as a good practical anæsthetic. When I began again to use it, a small proportion of chloroform was added; for the best English ethers were found to be very impure, and it was rare to get one with a specific gravity under .750. At length, Dr. Arthur Gamgee put into my hands a perfectly dry ether made from methylated spirit. It is manufactured by those conscientious chemists Messrs. Macfarlane. Its specific gravity is .715 to .717. It costs me three shillings a pound of twenty-four fluid ounces, and it answers admirably for local anæsthesia. For the last six or seven years, nothing but this ether has been used, except twice, when bichloride of methylene was given, and once, a few months ago, when operating at Newcastle, when chloroform was used. The apparatus employed has been the mask of Dr. Richardson's apparatus, with a sponge fixed in the bottom. It might easily be improved; but it answers its purpose well enough, though there is great waste with it. For many years, the ether was administered by my brother Dr. Keith; of late, it has been given by Dr. Foulis, who will at an early day give his observations upon it. There has been no difficulty in bringing patients under its influence. It is given freely, and plenty of air gets in with it. We have not observed the excitement which is said to accompany the inhalation of ether. It is always taken by the patient in bed, and no one is allowed to be in the room but the administrator and nurse.

But the great advantage of ether over chloroform in such operations as ovariectomy lies in the almost complete absence of after-vomiting. Vomiting with an open wound is of no consequence. With chloroform, after-vomiting was the rule, and, in the afternoon and first night of an operation, the nurse required to be always at hand with a basin for the vomiting. With ether, after-vomiting is quite the exception, and it is never severe or continued; while some patients sleep on, and often remain two or three hours without moving after being placed in bed.

My confidence in sulphuric ether as the best practical anæsthetic we yet have does not thus diminish. Its low specific gravity must make it less dangerous than the others. It is not perfect, but it answers my purpose better than any other. It saves my patients from the misery

of after-vomiting, and, in ovariectomy, from the chance of losing their lives in certain cases of bad adhesion from bleeding being set up by the sickness after the abdomen is closed. Whether of itself it diminishes the risk of operations, I cannot tell; but I am inclined to think that it does often save the feeble ones. This much I can say, that ether has now been given in one hundred and thirty-five cases of ovariectomy, and in two cases of successful removal of the uterus for fibro-cystic tumour. In every case, the anaesthesia was profound, many of the operations were very tedious, and, of the last sixty-six operated on, sixty have recovered.

In the beginning of 1848, Sir James Simpson wrote in the *Edinburgh Medical Journal* an elaborate statistical paper, showing that the mortality after amputations of the limbs, especially of the thigh, performed in hospitals under ether was much less than before ether was known. The results of upwards of three hundred amputations were obtained by circulars sent out in the usual way. This paper is worthy the attention of those interested in the statistics of the more recent results of operations in hospitals. Either chloroform has increased the mortality of hospital operations, or, in the early days of anaesthesia from ether, the results were better than at a later period. It may be also well to note that, when this paper was reprinted some years afterwards, the words ether, etherised, and etherisation were in almost every instance displaced by the words anaesthetic, anaesthetised, and anaesthesia. Perhaps the results of operations were then considered too good for ether, which latterly came to be given the merit of being only an improvement on the mandragora and other rubbish of the middle ages.

THE TREATMENT OF SYPHILIS BY MOIST MERCURIAL FUMIGATION.

By JAMES R. LANE, F.R.C.S.,

Surgeon to St. Mary's and the Lock Hospitals.

I REGRET that in some recent remarks on the modern treatment of syphilis, lately published in the *BRITISH MEDICAL JOURNAL*, I should have said anything displeasing to Mr. John St. S. Wilders of Birmingham, who writes in the *JOURNAL* of January 23rd in the character of an old pupil and friend of the late Mr. Langston Parker, and who thinks I have not shown sufficient appreciation of the system of moist mercurial fumigation, which that gentleman was the first to introduce.

In referring to the different modes of administering mercury, I said I believed it to be comparatively unimportant whether it were by the mouth, by inunction, or by fumigation. I said also, as quoted by Mr. Wilders, that "inunction is perhaps, on the whole, to be preferred, especially for hospital patients; but it is troublesome and dirty, and, therefore, it is often undesirable to resort to it in private practice. The same objection applies to fumigation, with the addition that it is, as a rule, more debilitating, for the nightly vapour-bath has a decidedly depressing influence." For these reasons, I prefer, in all ordinary cases, to administer the remedy by the mouth.

Mr. Wilders, on the other hand, "affirms with the utmost confidence that the treatment of syphilis by moist mercurial fumigation is neither troublesome nor dirty, nor has it a decidedly depressing influence on the patient; but that it is, on the contrary, a cleanly, rapid, and most manageable method, and the most powerful therapeutic agent in the removal of disease, and the least hurtful to the constitution of the patient." He then refers to Mr. Parker's large practice, and also to his book, in which ninety-one cases are to be found, many of them reported by Mr. Wilders himself, who "most fearlessly affirms that they are a trustworthy record of the marvellous efficacy of the treatment".

Mr. Wilders's zeal for the reputation of his late teacher (of whom I wish to speak with all respect) is greatly to be admired; but I cannot say as much for his logic. I would venture to suggest to this very affirmative gentleman that Mr. Parker's ninety-one cases, even with the addition of one of his own, which he gives in detail as a "reply to my allegations", have no bearing whatever on the question as to which plan of treatment should be preferred. They merely show that syphilis may be successfully treated by mercurial fumigation—a fact which is not denied; but they are worthless to show that fumigation is a better method than that by the mouth or by inunction. This point cannot be settled by assertions, however positive, but only by a careful trial of all three on a sufficient scale, and an impartial comparison of the results.

In forming the opinion which I expressed, I was not guided by what I had read in books, or what I had been taught by others, but by what I had observed for myself. Having no predilection for any particular method, and being desirous of learning whether any one of these three plans deserved to be preferred before the others, I was in the habit for years at the Lock Hospital of employing each in turn for a period of

months together in every case requiring mercurial treatment, and I failed to find any material difference in the results. In fact, I might easily have published a very large number of cases of each plan of treatment, showing equally "marvellous efficacy".

I know no reliable proof that fumigation is less hurtful to the constitution than the other methods, though nothing of course is easier than to make the assertion. Mercury, when given improperly, or in excess, will, I believe, be equally hurtful, by whatever channel it may be introduced into the system.

THE TREATMENT OF SCABIES.

By ROBERT LIVEING, M.D. F.R.C.P.,

Physician to the Middlesex Hospital, in charge of the Department for Skin-Diseases.

THERE are three principal methods of treating scabies: 1. By sulphuret of potassium baths; 2. By sulphur vapour-baths; 3. By sulphur ointment. It may be a satisfaction to those who cannot conveniently use the sulphur-baths, to know that the treatment by inunction of sulphur ointment is the most efficacious of the three methods.

There are three mistakes commonly made in treating scabies, especially in private practice: 1. In not applying the remedy over the skin of the whole body, except the head; 2. In using the ointment of the *British Pharmacopoeia*, which contains one part in five of sublimed sulphur, and is too strong, especially for children; 3. In using the ointment for too long a time, and thus producing an irritable state of the skin. This often happens when people attempt to treat themselves for what they believe to be the itch. On the two latter points, most experienced observers agree; but on the former some difference of opinion exists. In a lecture recently published, my friend Dr. Tilbury Fox remarks: "It is a rule of prime importance in treating itch, to accurately determine at the outset how far the acari have disseminated themselves about the body. The reason is obvious. There is no need to apply parasitocides to parts in which the acari do not exist, because the irritation and eruption elsewhere are due to sympathetic action; and these irritated parts will get well, if the acari be destroyed, and they do not require the use of irritant remedies, such as parasitocides are, but soothing remedies. The practice is to apply the remedy to every part of the body where eruption exists in cases of itch. Clearly this is wrong, from what I have just said. My rule is this: if the disease be recent, if it be only slightly marked, if it began about the hands, and there be no cuniculi about the penis, I order the parasiticide to be rubbed into the interdigital, the palm of the hand, and the wrists, and I apply a soothing lotion to all other irritable parts of the body. . . . I repeat, then, by way of summary, in private practice, if the disease be slight and recent, use the parasiticide to the hands only, and soothe the other parts with some emollient or astringent lotion or ointment."

In the first place, I would remark, that in private practice it is in many cases next to impossible, and quite unnecessary, especially in women and girls, to examine the abdomen, thighs, and every part of the body, to ascertain how much of the eruption is due to scabies, and how much to sympathetic action.

The best plan of proceeding is, in my opinion, as follows. Having once ascertained that scabies exists, order one thorough application at night of mild sulphur ointment to the whole of the body, except the head, and direct the patient to sleep in the drawers, jersey, and socks that he has used the day before: this will secure the death of any stray acari about the body or in his underclothes; in the morning, he should use a warm-bath. The after-treatment should consist of the local inunction of the ointment, into those parts only which are especially affected, for two or three nights. In all mild cases, the cure by this plan is quite certain, and is attended with very little inconvenience. The objections to sulphur-ointment are its irritating qualities and its smell. The first is avoided by using an ointment made with half a drachm to two scruples of the precipitated sulphur to one ounce of lard. The precipitated is in finer powder, and less gritty than the sublimed sulphur, and more efficacious. A great part of the inconvenience arising from the smell of the sulphur may be avoided by using it only during the night. A drop or two of sandal-wood oil will quite disguise the smell. In cases of long standing, it is necessary to have the clothes baked; but a temperature of 100 deg. to 200 deg. Fahr. is quite sufficient, and the bed may be easily fumigated by using a little sulphur sprinkled on the cinders (not too hot) of a warming-pan.

It often happens that the irritation of skin remains after the scabies is cured, and thus induces people to go on with the sulphur treatment too long. Instead of doing so, a mild stavesacre ointment should be used, made with the oil of stavesacre and lard: this relieves the itching, and at the same time will kill any stray acari that may have escaped death from the sulphur.

MALARIA.

By J. BUTLER HAMILTON, M.D.T.C.D., Surgeon, Army Medical Department, Fort Pitt, Chatham.

For some weeks, the pages of the BRITISH MEDICAL JOURNAL have contained a most interesting discussion on the above subject, provoked in the first instance by a critique on Dr. Munro's paper in the last Army Medical Blue Book written by Surgeon-General Maclean, and followed up by rejoinders from Dr. Inman and Dr. Tilt.

On first reading Dr. Munro's paper, I was struck by the apparent subtlety of his arguments, and was almost persuaded against my own experience and conviction; but, on reading Dr. Maclean's rejoinder, I quite saw all the weak points in Dr. Munro's argument, and I think we all owe a debt of gratitude to Mr. Maclean for putting matters so clearly before us. Dr. Inman seems to me to take up a most untenable position; and, while having the honesty to acknowledge he has no practical knowledge of malaria, he attempts, from the rostrum of his study-table, to dictate to those who have not only spent the best part of their lives in treating the diseases caused by malaria, but who have also in too many cases suffered in the flesh from the same cause.

I will briefly review Dr. Inman's last arguments. He states that on board ship "the folks attacked are not those who sleep between decks, but those who sleep in the open air". Now, I have had as large an experience at sea as most medical men not actually belonging to the navy, and have myself slept night after night on deck in the tropics for weeks, and never once was attacked by ague in consequence. I have sailed the West Indies from one end to the other, also in that most pestiferous region tropical America; and though, as a rule, I slept on deck, often under no awning, and merely lying down in my clothes on a bench or on a grating, yet I never once got an attack of intermittent fever in consequence. It is a well known fact that, in these malarious regions, the custom is to anchor at night as far from land as possible, in order to avoid the pernicious effects of the land-breeze; in other words, of malaria.

Dr. Inman says bilge-water is "a nearly constant quantity in ships". This I deny. I have sailed in ships so dry and free from bilge-water, that the captains used to pump water into them and pump it out again merely as a matter of precaution, and to keep them "sweet". Dr. Inman accuses Dr. Maclean of talking "vaguely about rotten granite, fungi, water below the surface, old wells, etc.", and then immediately goes off himself and talks in the vaguest manner about there not being "a spot on the earth's surface where water cannot be found by those who dig for it". Now it is this very point that is the all-important one in furnishing one of the chief factors of malaria. I look on the depth at which subsoil-water is found as one of the most likely indications of any given place being malarious, or the reverse; and, *ceteris paribus*, it will be found that the nearer the surface the subsoil-water lies, the more malarious the locality.

At Belize, in British Honduras, the barracks are built on the alluvial delta of a large river which, flowing for miles through and draining in its course an enormous tract of swamp, empties itself into the sea by two mouths on each side of the site of the barracks. The ground on which the barracks are situated is below the level of the sea at high tide, so that the subsoil-water lies quite close to the surface—so close, in fact, that I made a well by merely sinking an old packing case, with a few holes bored in the bottom, about eighteen inches below the level of the ground, and used the water for my bath. To the rear of the barracks lies a foul swamp, extending back for miles, and, as might be expected, the cause of malarious diseases to a fearful extent: to prove this further, when the sea breeze blew, the place was fairly healthy; but, when the land-wind set in, bringing with it its load of malaria, agues became fearfully prevalent.

I will also give an example from India. Allahabad is situated on a loop of land almost surrounded by the Ganges, and about five miles in length. The old cantonments were situated at the extreme end of the loop, which was fairly elevated about fifty feet above the level of the river, the subsoil-water averaging a depth of forty feet; the new cantonments are built near the railway, chiefly for strategic reasons, I believe, and the barracks are placed on a low swampy piece of ground, in which the subsoil-water is found about twelve feet from the surface. The new barracks have all the advantages of the latest construction in elevation from the ground, the men sleeping on the upper storeys, while in the old cantonment the barrack buildings were little better than sheds; yet in the former malarious fevers prevailed in an enormously larger proportion than in the older, but better situated, buildings. The climate was the same, and the men were not more exposed to "chill" in one than in the other; but the malarial factors

existed in a much more marked degree in the new than in the old cantonments.

Dr. Inman next attacks the theory concerning the causation of malaria by the turning over and exposure of earth, and wants to know why ague is not equally prevalent at Chatham and Portsmouth as at Hong Kong. He might as well ask why, if one man contract small-pox from turning over the rags in a rag-dealer's store, every man who sifts rags in other stores does not equally take small-pox? The answer is obvious: in one the factors of the disease are present in the shape of clothes or bedding used by small-pox cases; in the others, not so. It is the same with malaria. Surely it cannot be thought by Dr. Inman, or anyone else, that Dr. Maclean ever meant to be understood that the mere act of turning over the soil would produce malaria. No; the factors must be present, *i.e.*, decomposing vegetable or other substances acted on by moisture and a certain temperature.

One of the worst outbreaks of malarious fever I ever remember took place at Jubbulpore, in the Central Provinces, in the autumn of 1866; and the 23rd (Royal Welsh) Fusiliers, then quartered there, suffered to a fearful extent. I forget the actual number of deaths, but there were about 20 out of a strength of 500, nearly every man present having been attacked, and at one time there were nearly 300 men under treatment; oddly enough, the battery of Royal Artillery of which I was in charge not only escaped all mortality, but had hardly a case in hospital, though occupying the same range of barracks. Now, there were three causes in my mind that led to this result. The buildings occupied by the Fusiliers ran along the edge of a plateau, below which was a large extent of swamp, and they shut out our barracks almost entirely from the influence of the malaria. The next cause in my mind was in the fact, that the large surface-drains running through the lines of the 23rd had been just opened and cleaned out, while those in our portion of the cantonment were not interfered with. The third reason was, I gave every man in the battery three grains of quinine every morning as a prophylactic, while the surgeon of the "Royal Welsh" was compelled to abstain from doing so, in consequence of an order received from the Deputy Inspector-General of the circle (Indian Medical Service), who had the issue of medicines in his power. I disobeyed the order on my own responsibility with the happiest results; and, when the mischief was done, the issue was carried out with the 23rd. I well remember the packets of quinine arriving daily by post, the old adage of "locking the door when the horse is stolen" being peculiarly applicable.

Regarding the effects of sleeping under cover, I quite agree with Dr. Inman in his advice on that head; and there is no doubt that, when in a malarious place, it is advisable not to expose the body to chill; not that I think chill produces malarious diseases in a healthy person, but anything that tends to lower the tone and reduce the general health assists the enemy in his work, and lets in the fatal malaria by a loophole.

When the blood is saturated with the malarious poison, a very small cause will suffice to induce a paroxysm of ague. It is now just fourteen years since I got my first attack, and it was in this wise. Returning from Carosal to Belize in a small open schooner, we grounded on an alluvial island at night, and for two days we stuck there, in consequence of a change in the wind, which lowered the height of the water within the reef that runs all along that coast. Expecting to make Belize the evening of the day we started, I took no provisions with me, so had to land on the island and shoot pigeons for food. For several hours, I wandered about in the rotten mud of this swampy spot, preferring the coolness of the shade to the heat of the open boat; in addition to which, we had to drink the semi-putrid water we found there. I got no "chill", as at night I had on abundance of clothes and blankets; nevertheless, on my arrival at Belize, I was attacked by malarious fever, which all but proved fatal, and which I never entirely succeeded in shaking off for over a year, some of the worst attacks I ever had being in Dublin, after my return home on sick leave. Certainly I will allow chills and exposures often induced paroxysms of the ague, but I deny that they ever caused the disease originally. Affections of the mind, it is well known, often induce ague attacks in the victims of malaria, and the worst attack I ever had came on the day I was to go before a Board which was to decide on my fitness or otherwise to return to the West Indies. Even at this period of time, if I catch cold, it always assumes a periodic form, and quinine is my sheet-anchor.

Dr. Inman speaks confidently about chills producing ague. I will open a fine field for his investigation. Let him inquire whether gardeners, who work much in greenhouses kept at a high temperature, and who must often be chilled by sudden exposure to the outer air, are more liable to get ague than others residing in the same locality. Again: firemen on board steamers, after being for a couple of hours in the fearful heat of the stokeholes, constantly expose themselves to

chills by coming on deck to get cool; and, though acute inflammation of the lungs is by no means uncommon, yet I think he will find it hard to prove they are more liable to ague than the other seamen on board. The most deadly spot in the world probably, exceeding even the coast of Africa in the intensity of its malaria, is the "Terai"—that belt of jungle running along the foot of the Himalayas: for an European to enter it at certain seasons of the year, is almost certain death. Here is a true example of malaria produced by the well known factors, vegetable decomposition, moisture to saturation, subsoil-water almost at the surface, and a high temperature. Here it is not necessary to be chilled, and no number of blankets will keep off the deadly malaria; but, twenty miles off, one may sleep in the open with almost perfect safety, excepting, perhaps, at the end of the rains, when, all the factors of malaria being present in a greater or less degree, every part of the continent of Hindostan is more or less malarious.

I fear I have been not only prolix, but egotistic, in the above remarks; but experience in one's own person is more valuable than the parlour arguments of a man who tries to upset the conclusions arrived at by such men as Dr. Maclean, who have spent their lives not only in seeing, but in suffering from, the effects of malaria.

AN OPERATION FOR THE DESTRUCTION OF VARICOSE VEINS.

By CHARLES STEELE, F.R.C.S.,
Surgeon to the Bristol Royal Infirmary.

It is but waste of time to heal varicose ulcers without destroying the varicose veins on which they depend, as they are sure soon to break down again. Varicose ulcers whose veins have been destroyed immediately assume a healthy aspect, and heal much more rapidly from being relieved of chronic congestion. If the continuity of a vein be destroyed at any point, the entire vein beyond that point withers up to the nearest branch.

Until rather more than a year ago, I always performed the operation of ligation with pins and wire, and subcutaneous division. But at that time a young man came under my care in the Bristol Infirmary with bad varicose ulcers, and varicose veins standing out prominently above them. I told him it would be necessary to destroy the veins; but he replied, "No, thank you, sir; I had them pinned a year ago, and they have come again as bad as ever, and in consequence I will not have them operated on again". I had often remarked, when operating, how easy it would be for a vein to be only partly cut through, the blood to escape, and the surgeon to presume that the vein was severed; in fact, that it is difficult to prevent a narrow band of tough vein from slipping over the point of the bistoury. Besides this, presuming even that the vein is entirely cut through, the ends lie in apposition still, the vein is held open by its adhesion to contiguous parts, and many varicose veins are as thick walled and rigid as India-rubber tubing; it is easy then, when the clots have become absorbed, for the circulation to be re-established. It struck me that the most satisfactory plan would be to cut down on the vein, and remove a portion at a suitable point.

A fit case soon presented itself, in the person of W. H., who was admitted into Ward 11 of the Bristol Infirmary, on December 29th, 1873, with an indolent ulcer on the right leg, from which the varicose internal saphena ran straight up to the inner side of the knee. On January 2nd, 1874, I made an incision along the vein three-quarters of an inch in length over the inner tuberosity of the tibia, passed a blunt hook under the vein, dragged out as much as I could, and cut off a piece half an inch long, applied a pad of lint saturated with compound tincture of benzoin to the wound, simple dressing to the ulcer, and bandaged the leg. Very little blood was lost. When examined two days afterwards, the ulcer was changed to a healthy granulating surface, and the wound looked well. Ten days afterwards, a slight attack of erysipelas (which was prevalent at the time) attacked the leg, but passed off soon, doing no harm beyond delaying the healing process. The wound healed by second intention, and the vein became reduced to a small, hard, solid cord.

I was satisfied with my first, and soon tried the same plan on another and worse case. Ann B. had suffered for years from very bad varicose veins of both legs, especially the right, from the middle of which the internal saphena expanded into a bag or coil, forming a swelling two and a half inches long and one inch wide, in the whole of which fluctuation was easily felt, and impulse on coughing was as distinct as in any hernia. The antero-internal surface of both legs was of a deep brown, almost black colour, scattered with numbers of blue elevations, which consisted of varicose bulges covered with skin as thin as paper, all ready to burst; and on each ankle was an indolent ulcer. I removed

portions from the leading veins at the inner side of each knee, with the effect of improving the ulcers, and stopping absolutely the impulse on coughing. But, after three weeks, finding that the swelling contained some blood, and that the veins had communications with deep veins, so that they filled with blood in the lower part on the legs being hung down, I cut on to the large swelling, and removed transversely its central portion, which consisted of several tubes matted together. I also lanced each prominent bulge, and stuffed lint into the cavity. The result was good: all healed by granulation, the veins were totally destroyed, the ulcers healed, and the patient was freed from the intolerable pain, weight, and weariness which, endured for years, had rendered her thin, weak, nervous, and timid. Having heard that it was with great difficulty she was persuaded to seek any advice, I felt it essential to make an absolute cure of her at once, and have since seen her walking very comfortably.

I have operated in a similar manner on several other patients without any bad results, but with uniform success. Two other cases deserve particular mention.

A farmer, living at a distance, consulted me last autumn, on account of a small troublesome ulcer of several years' standing on his right leg, resulting, he considered, from having broken his leg ten years ago. He was very lame, required a stick, and, if he walked more than a very short distance, endured much pain and swelling. I found an irregular ulcer, deep discoloration, great chronic congestion, and œdema. No leading varicose vein could be discovered; but he had fifteen blue prominent bulges on the front of the upper part of the leg. He took lodgings in Bristol, and I laid open each of these bulges (they were too small to excise); ascertained with a probe that each vein had a free opening into it, and inserted a stick of chloride of zinc into each. The result was a series of small sloughs, followed as they separated by granulation, and ultimately cicatrization of the original ulcer and of each wound, subsidence of œdema, congestion, and lividity, and recovery of power to walk easily without a stick for a long distance.

Mrs. F., a hard-working woman, the mother of several children, came under my care, on account of a large, painful, excoriated surface on her left ankle, which was quite misshapen by great œdema. I found that the veins of both legs were very varicose, while the left saphena in the middle of the thigh became so tortuous and dilated, that it developed into a tumour three inches long by one inch broad, prominent and blue. After subduing irritation by rest, etc., I cut out portions on each leg below the knee of the internal saphena, and of a leading anterior branch which fell into it. I found that the varicose mass in the left thigh, when emptied, filled again, owing to some deep communication, and accordingly treated it as I should a fatty or other tumour: made an incision in its long diameter, dissected it freely loose, and tore away each end with a pair of forceps. A little irritation followed, but soon passed off; the wounds on the right leg healed by first intention, those on the left by granulation, the excoriation healed, and the œdema subsided. The day before she went out, she was up, and I asked her to walk the length of the ward, which she did very briskly. A gentleman present asked, "Do you walk better than you did two months ago?" She replied, "I have not walked so well, sir, for five years." After she had been at home at her duties for some weeks, she made the same statement.

The method I adopt now in an ordinary case is to isolate the main vein or veins below the knee, compress above to define the vessel, make an incision at right angles to its axis, dissect out the vein without pricking it, seize firmly with torsion-forceps, and drag out as much as possible, which seldom amounts to an inch, and cut off the piece as close to the skin as possible at both ends. I pass a probe through the removed piece, to be sure that the entire calibre is secured. The vein in the leg is emptied of blood by pressure: if it do not refill, I am satisfied; if it do, I remove portions which are prominent below. A horsehair suture in the wound, a compress of cotton-wool and flum bandage complete the operation. After trying several dressings, I prefer the simple cotton-wool, as it soaks up blood and forms a good protection, which drops off like a scab, if healing by the first intention occur, and comes off easily, from becoming moist, if suppuration take place.

SURGICAL MEMORANDA.

MR. MARSHALL'S METHOD OF TREATING VARICOSE VEINS.

I AM sure it will interest Mr. Marshall to know that, on November 7th last, I operated with complete success on a young gentleman suffering from very aggravated varicocele, in the following manner. The principal enlarged and tortuous spermatic vein was exposed for about three

inches by an incision made through the scrotal and inguinal textures. A ligature of prepared catgut was then applied round the upper and lower portion of this exposed vein, and the part of the vessel included between the two ligatures was cut completely away. The portion of vein thus removed was fully two inches in length. A piece of lax scrotal skin was also cut away, and the edges of the wound being brought together, carbolic acid dressing was applied. The result has been perfect, and I am thus glad to be able to confirm Mr. Marshall's experience of this method of treating varicose veins.

THOMAS ANNANDALE, Edinburgh.

CLINICAL MEMORANDA.

MUSHROOM POISONING.

IN the JOURNAL for January 9th, Dr. Hutchinson published, under the above heading, a case which terminated fatally. The mushrooms were eaten on a Monday night. Although the patient had previously been rather unwell, no vomiting or diarrhoea followed, but, on the subsequent Friday, febrile symptoms gradually came on, accompanied by cerebral excitement, and a rash, which is vaguely described as "similar to that seen in some people after having eaten shell-fish". Death took place in about a fortnight. Now, as setting aside all other considerations, no poison, (excepting, of course, those of the septic class) has any period of incubation whatever. I fail to understand how Dr. Hutchinson can, for a moment, have attributed to mushrooms the symptoms of what was probably an ordinary attack of typhoid fever (or scarlatina?); and I fully agree with Mr. Cutie in believing, that the true mushroom "never acts as a poison, in the ordinary acceptation of the word".

HERBERT L. SNOW, M.D.

DR. LAIDLAW PURVES'S NEW OPTOMETER.

I HAVE read with interest Dr. Purves's remarks upon the determination of the refraction of the eye, and also the description of an instrument which he has devised for determining its various conditions. Dr. Purves, like many other inventors of new instruments, must not feel disappointed if it be subsequently pointed out that they are in reality old. Two years ago, I had constructed the exact instrument which Dr. Purves describes, and have given a full account of it in a small book published by me last year, entitled *Aids to Ophthalmic Diagnosis*. The only difference between my instrument and that of Dr. Purves is, that mine is smaller, and so can be held in the hand; also an ophthalmoscopic mirror can be adjusted to the front, so that it is, in fact, an ophthalmoscope and optometer combined. The powers which I employed in the discs which revolve in front of each other were, + 4, 5, 6, 9, 15, and 20; and the subjoined table will allow any one to see at a glance the reaction which any one glass will have upon another.

	- 4	- 5	- 6	9	- 15	- 25
+ 4	neut	+ 20	+ 12	+ 7 $\frac{1}{2}$	+ 5 $\frac{1}{2}$	+ 4 $\frac{1}{2}$ ^a
+ 5	20	neut	+ 30	+ 11 $\frac{1}{2}$	+ 7 $\frac{1}{2}$	+ 6 $\frac{1}{2}$
+ 6	- 12	30	neut	+ 18	+ 10	+ 7 $\frac{1}{2}$ ^b
+ 9	- 7 $\frac{1}{2}$	11 $\frac{1}{2}$	- 18	neut	+ 22 $\frac{1}{2}$	+ 14 $\frac{1}{2}$ ^b
+ 15	- 5 $\frac{1}{2}$	- 7 $\frac{1}{2}$	- 10	- 22 $\frac{1}{2}$	neut	+ 37 $\frac{1}{2}$
+ 25	- 4 $\frac{1}{2}$	- 6 $\frac{1}{2}$	- 7 $\frac{1}{2}$ ^b	14 $\frac{1}{2}$	37 $\frac{1}{2}$	neut

The column at the top is that of the minus disc; the column at the left is that of the plus disc; and the power which will result from the combination of any two glasses will be found at the angle of a line drawn from each. The numbers, both positive and negative, which we are able to produce by the various combinations of the two discs, are as follows: 4, 4 $\frac{1}{2}$, 5, 5 $\frac{1}{2}$, 6, 6 $\frac{1}{2}$, 7 $\frac{1}{2}$, 7 $\frac{1}{2}$, 8 $\frac{1}{2}$, 9, 10, 11 $\frac{1}{2}$, 12, 14 $\frac{1}{2}$, 15, 18, 20, 22 $\frac{1}{2}$, 30, 37 $\frac{1}{2}$. The numbers marked with an asterisk are not quite

the correct numbers, but differ from them only by fractional quantities: thus, 4 $\frac{1}{2}$ is really 4 $\frac{1}{2}$ + $\frac{1}{2}$, etc.

Personally, I have not been well satisfied with the working of this instrument as an optometer; partly because it was small; and partly because, in using it, one had to have frequent recourse to the table of calculations. Dust was continually insinuating itself between the glasses, and there was some difficulty in cleansing them. Mr. Robson, the optician, of Newcastle, has just finished, under my supervision, a new optometer for the Eye Infirmary of this town, which I think will obviate all difficulties, and an account of which I shall publish shortly.

CHRISTOPHER JEAFFRESON, F.R.C.S.E., Newcastle-on-Tyne.

CHILL AND MALARIA.

HAVING read the controversial letters in the BRITISH MEDICAL JOURNAL on chill and malaria as causes of paroxysmal fever, I beg to cite one case that occurred in my own family, in which the cause, beyond all doubt, arose from disturbance of the soil. A lady, whose customary sitting-room looked out on a wide gravel walk, enjoyed her usual health until the gravel, which had not been disturbed for years, and was in consequence moss-grown and very damp, was turned up by the gardener. She became directly afterwards affected with an attack of ague, a disease she had never suffered previously, and which was not prevalent in the neighbourhood. I believe it was found, in the Peninsular War, that the troops who were encamped on ground which had been some time previously partly under water, and subsequently dried by the sun, suffered more from intermittent fever than others. I cannot suppose any one would consider Dr. Oldham's test any proof, unless that "the exception proves the rule"; and, after reading Dr. Divorcy's letter, I should say that "a physician in his bedroom, if not in his study", is very well calculated to bear witness in the matter under inquiry. When in Central America, some years ago, I was informed that the railway from Colon to Panama, across the Isthmus of Darien, cost a life for every "sleeper" laid down; the mortality being partly due to the disturbance of the humid soil.

J. HAWKES, M.D., Alton, Hants.

THERAPEUTIC MEMORANDA.

TREATMENT OF ASCARIS LUMBRICOIDES.

THERE are few children who do not suffer more or less from intestinal worms. Although such cases occur almost daily to the medical profession, and although we have remedies which are known to act beneficially, there are few cases in which we are less successful in making a permanent cure; and all because enough care is not given to the manner in which those remedies are administered, and to dietetics during their administration. The following case is mentioned, not by way of offering anything new as a remedy, but simply to impress on the profession the desirability of giving it in the way I shall record. J. D., a little girl two years and a half old, came under my care some time since. I was told by the mother that she had been for some time back occasionally passing a few worms, and that she had lately on two different occasions vomited one. I happened to see the last one vomited, and found it to be the ascaris lumbricoides. The child was thin, weak, pale, and fretful. For the expulsion of those worms, I have the greatest confidence in santonin. It has, besides, the advantage of being easily given to children when compounded with a little sugar. I accordingly gave her three powders, each containing four grains of santonin, with orders to take one each night at bedtime. Before giving the first one, the bowels were opened by a gentle aperient; and, during the administration of the santonin, the child was kept on soups and broths. On the morning of the fourth day, I administered a brisk purgative composed of calomel and jalap. During the course of the day, the child passed fifty large worms. Their average length was about nine inches. A tonic course of treatment was afterwards adopted, and the child has improved rapidly, and now presents no trace of her former illness. The santonin should always be given for three or four days before the purgative. To give it with, or only once before, a cathartic is not sufficient. It acts toxically, and must have time to do its work. The worms are passed like other fecal matter when dead; but, so long as they are alive, no amount of purging will bring them all away. I have every confidence in the power of this drug to remove completely the lumbricoides worm, and can recommend it as a specific in such cases, when used in the manner I have described.

GEORGE CALDERWOOD, M.D., Egremont.

OBSTETRIC MEMORANDA.

DOUBLE ARM-PRESENTATION.

IN reference to the case of double arm-presentation which appeared in the BRITISH MEDICAL JOURNAL of December 10th, I beg to state that I was called to one exactly similar, by the late Mr. Watson of Drumlithin, on April 20th, 1857. Mrs. C. had been in labour all the previous day. Chloroform was administered. I returned both arms, and then brought down the feet. Mrs. C. had a good recovery, and I attended her again thirteen months afterwards.

JOS. HENDERSON, L.R.C.S. Ed., Auchinblae.

REPORTS

OF

MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

ST. BARTHOLOMEW'S HOSPITAL.

CASE OF EXTRA-UTERINE FETATION.

(Under the care of Dr. GREENHALGH.)

[Reported by Dr. HOPE.]

E. R., AGED 39, was admitted on September 10th, 1874, when the following facts were elicited. She stated that she had been married twenty-two years, and was the mother of one child, now twenty-one years of age. She had never miscarried. The catamenia, which commenced when she was fifteen years of age, occurred every month, and usually lasted three days, and were somewhat scanty and painful. She was last "unwell" six weeks ago. Her general health, which had never been good, had been worse since her confinement. She stated that four months ago she took cold just before a catamenial period, since which she had not menstruated regularly. At that time, she suffered much from shooting pains "between the front and back passage", followed in a fortnight by pains in the hypogastrium, like those of labour, and accompanied with fainting-fits, when the abdomen became much distended with flatus, which, however, passed off after taking an aperient. She experienced another attack a month afterwards, similar attacks having occurred regularly for the three last successive fortnights.

On admission, she complained of a dull heavy pain above the pubes, and a feeling of great abdominal distension. On examination, the abdomen was greatly distended and tympanitic. In the right iliac region was an oblong dense tumour, somewhat tender on pressure. The vagina was moist. The os uteri was patulous, and the cervix, which was somewhat elongated, was cedematous to the touch, much raised, and was pushed against the pubes. The posterior *cul-de-sac* of the vagina was occupied by a hard, uniform, immovable swelling, not tender on pressure. The breasts were quite flaccid, and there was no trace of areolæ. No foetal heart-sounds could be heard. The uterine sound was not introduced.

On the 13th, there was a discharge of blood from the vagina, accompanied with great pain and forcing, which lasted for one night only. On the 17th, there was another loss, "like a poorly time", rather free and clotted, with great pain, which continued more or less for four days. She was ordered bromide of potassium, with bark.

For two days her condition was somewhat improved, but on October 19th she was seized with pain in the epigastrium, flatulence, and bilious vomiting, quick pulse, and much constitutional disturbance, which continued for three days, when, upon examination *per vaginam*, the swelling posterior to the uterus was found to have become more or less boggy. She was ordered opium, etc.

On October 29th, a fine trocar was passed into the most depending part of the swelling, posterior to the uterus, which was followed by the escape of some grumous-like fluid.

On November 1st, there was a large escape of a muco-purulent discharge *per rectum*, which gave great relief to her sufferings.

On November 2nd, about a pint of thin sanious fluid came from the vagina. The abdominal pain still persisted. Tongue clean; pulse quick. She was ordered a saline draught, and a vaginal *douche* with Condy's fluid.

On Nov. 5th, there were pain and feverishness; the abdomen was much distended and tympanitic. The swelling posterior to the uterus had now become much reduced in size, and the os uteri could be more easily reached.

On the 9th, she was much relieved. The vaginal discharge had ceased, but the bowels were much relaxed. An opiate enema was ordered.

On the 12th, the uterus had assumed a more normal position, apparently due to the decrease in the size of the swelling. The diarrhoea still persisted, and the evacuations were very offensive.

On the 16th, she had great abdominal pain, and almost incessant vomiting; the pulse was excessively weak; the countenance anxious and shrunk; the extremities were cold, notwithstanding that the bowels had been less relaxed; and every endeavour, by opium and other means, were had recourse to, in order to support her flagging powers. Still the symptoms of collapse rapidly increased, and she sank in the morning of November 17th, nearly two months after her admission.

POST-MORTEM EXAMINATION, thirty-four hours after death. Through-out the abdomen were well-marked evidences of recent peritonitis. About three feet above the ileo-cæcal valve, was a band of omentum crossing the small intestine, and constricting it so tightly that no air nor fluid could be passed through the constriction. Above the obstruction, the intestine was much dilated and distended by faeces; below, it was empty and collapsed. Rising out of the pelvis, and occupying chiefly the left iliac fossa, was a large tumour filled with blood, which was found to contain the remains of a fetus of about six months. The placenta and cord being in a most decomposed condition, and emitting a horribly fetid odour. The walls of the uterus were much hypertrophied, and the uterus was nearly four times its normal size. The os uteri was soft and spongy, and the cervix was occluded by a thick and dark gelatinous mass. No decidua could be detected. The vagina was of a purplish colour.

On examining the cyst more closely, it was found to be firmly adherent to the anterior wall of the rectum; and, about six inches from the anus, was a round opening about the size of a shilling, having perfectly smooth edges, which communicated with the interior of the cyst. The mass of the cyst lay low down in Douglas's pouch, and in front and to its left side was a ragged opening about four inches in extent, at which point the cyst had ruptured. Much of the Fallopian tube on that side had been cut away, so that it was difficult to trace its connection with the cyst; the probability, however, being that the case was one of tubo-ovarian fœtation.

REMARKS BY DR. HOPE.—The diagnosis of extra-uterine fœtation is not always easy; nor are the evidences of pregnancy always sufficiently well marked, though usually there are very presumptive proofs of its existence. In the above case, the clinical history and the local conditions pointed rather to the presence of a retrouterine hæmatocele, as not only were there many prominent symptoms of that affection (such as periodic pains low down in the pelvis, faintings, and aberrations in the menstrual function), but, at the same time, there were the negative signs of pregnancy as indicated by the breasts, and the external abdominal tumour. The character of the swelling was also significant. It was low down in Douglas's pouch, and occupied the greater part of the pelvic cavity posteriorly, the uterus being pushed forwards against the symphysis pubis. At first, it was hard and uniform to the touch, but ere long became soft and boggy, as though suppuration were imminent; and this, accompanied by much constitutional disturbance, and a general aggravation of the local symptoms. The practical question now at issue lay as to the expediency of surgical interference. Nor was it of small importance under the doubtful nature of the case; for, on the other hand, had the diagnosis of hæmatocele been quite conclusive, for even an exploratory puncture is not always free from risk. Opinion on this point has differed widely, and perhaps the dangers of puncture are less considerable than have been supposed. I think, however, that in this case the duration of the swelling, and the sudden supervention of acute symptoms, was a sufficient indication for such a procedure. What influence this exploratory puncture had upon the ultimate issue of the case, it would be difficult to determine.

Probably about this time the rupture of the foetal cyst, and its communication with the bowel, was imminent. Very soon a profuse muco-purulent discharge *per rectum* occurred, followed by persistent diarrhoea of a most offensive character, which for a time relieved her sufferings, and might even have ended in the ultimate recovery of the patient, had not extensive peritonitis, rupture of the cyst, and a sudden effusion of blood into the peritoneal cavity, speedily proved fatal. It is worthy of note that the deciduous membrane could not be detected, but that a gelatinous substance—a kind of thick ropy mucus—was found in the neck of the uterus.

ROYAL HANTS COUNTY HOSPITAL.

CASE OF TUBERCULAR MENINGITIS.

(Under the care of Dr. BUTLER.)

[For the report of this case, we are indebted to Mr. WM. ROBERT SMITH, Resident Surgeon.]

H. B., AGED 13, was admitted into the Hospital, under the care of Dr. Butler, on September 24th, complaining of stiffness and swelling of the right knee. He had always enjoyed good health up to four months before this, when he thought he strained his knee, since which time he had had occasional pain and difficulty in walking.

He was a stout healthy-looking boy, feeling quite well in his general health. The tongue was clean, the bowels regular, the appetite good; he had no cough, the urine was normal. The chest was well formed; the percussion-sound and respiratory murmur were good; the breathing-sounds, however, were somewhat harsh at the left apex; the knee was rather swollen, but there was no tenderness or pain; there was slight effusion into the joint. The leg was placed on a back splint, and swung, a linseed-meal poultice applied, and the ordinary full diet ordered.

October 20th. The effusion of fluid had increased, but he did not complain of pain. A blister was ordered to be applied.

From this date, the fluid gradually diminished in quantity until it entirely disappeared, and the patient continued in good health until November 17th, when he complained of headache and giddiness. He vomited once after taking his medicine; the tongue was furred; the bowels confined; pulse full, 100; the knee was red, hot, and painful. Simple effervescing saline medicine was given, and evaporating lotion was applied to the knee.

November 18th. He was much better. The head was less painful; the bowels had been well moved.

The boy continued in much better health until Christmas Day, when he became very drowsy and indifferent. He did not complain of pain in the head. The tongue was furred; the bowels regular; appetite very bad; pulse 100, full. He cried out with pain in the knee when it was moved or touched.

December 26th. He slept badly during the night, muttering and crying out occasionally, but always lying with his head buried in the bed-clothes. The patient looked bewildered, was dull, heavy, and stupid, and quite speechless, but apparently understood questions put to him. There was no tenderness about the head or spine, but a general rigidity and tonic spasm of the whole of the body, especially the arms and abdomen. He swallowed with difficulty. The face was flushed; the pupils widely dilated; the tongue furred but moist; the bowels confined; temperature 102; pulse 120.

December 27th. He was in much the same condition, but rigidity was increased. The eyes were injected; he passed urine and feces involuntarily. Temperature 101; pulse 135, full.

December 28th. He remained in much the same state.

December 30th. On the whole, he seemed rather better; the rigidity was less. He made an effort, when requested, to put out his tongue, which was seen to be furred and moist. The pupils were contracted. Temperature 100; pulse 126. He still took nourishment badly.

December 31st. He was more dull and stupid; his rigidity was quite gone. Temperature 99; pulse 120.

January 1st. He was sinking fast; the pupils were dilated and insensible to light; the extremities cold. At 12 P.M., he died quite quietly.

NECROPSY twenty-four hours after death. Rigor mortis was present. The dura mater was much congested. On the under surface of the brain, immediately in front of the pons Varolii, and around the optic nerve, was effusion of lymph. The pia mater in the Sylvian fissures was thickly studded with tubercles, more especially in the right. The brain was firm; the lateral ventricles contained about four ounces of clear serum. The left pleura was slightly adherent; the right lung contained a few tubercles at its apex. The left lung was thickly studded with milium tubercles throughout its entire substance. The heart was normal. The liver was of normal size, but contained several tubercles. One or two tubercles were found in the capsule of the spleen. The kidneys were normal; the intestines were normal; the ileum was slightly congested. The inner semilunar cartilage of the right knee was much ulcerated; the inner condyle of the femur was disintegrated and softened. There was no fluid in the joint.

REMARKS BY MR. SMITH.—This case appears to me to possess some interest, from the absence of several of those symptoms which generally indicate the advent of tubercular mischief in the brain, as also from the difficulty which was experienced in the earlier stages, of diagnosing it

to be a case of tubercular, instead of simple meningitis; more especially as it occurred in a boy of apparently good health, with no history of phthisis, and no symptoms of tubercular deposit in the lungs. The points which mainly assisted in the arrival at a correct diagnosis were—the absence of acute pain, of intense fever, and intolerance of light and sound. The patient from the very first was quiet and motionless, rarely crying out, and then never as if in pain. The rigidity of the abdominal muscles, with stiffness of the lower jaw and difficulty of swallowing, were most marked, and closely resembled tetanus; but the speechless condition of the patient, with the bewildered look and heavy expressionless countenance, pointed to the true source of the disease. I think it, however, worthy of note that there were never fixed pain or tenderness in the forehead or any other part of the head, no convulsions or twitchings, and no vomiting.

The treatment adopted was throughout more particularly directed to the support of the vital powers—milk, eggs, beef-tea, and brandy being given by the mouth, and, when this became impossible, by the rectum.

SELECTIONS FROM JOURNALS.

THERAPEUTICS.

A NEW SIALOGOGUE AND SUDORIFIC.—Mr. Martindale, a well-known pharmaceutical chemist of London, has pursued some further experiments with jaborandi, employing himself as the subject. He gives an account of them in the *Pharmaceutical Journal*, from which we extract the following. Having heard doubts expressed about the activity of the jaborandi last received, as compared with the results obtained in the first trials I witnessed at University College Hospital, I became somewhat sceptical about its efficacy, and, therefore, expecting to get little results, tried it upon myself. To me the effect seemed simply marvellous. I made an infusion of sixty grains of the bruised leaf in five ounces of boiling water, let it stand fifteen minutes and strained it. On pouring the water upon the drug, I noticed the characteristic odour almost entirely disappeared. The infusion was of a pale sherry colour, had a mawkish bitter taste, but did not excite the glowing heat upon the tongue that the leaf itself did; this I thought strange, and, on tasting the drugs, I found they still retained their pungent taste when chewed. It was evident to me that, if its diaphoretic properties depended on the principle having this pungent taste, boiling water does not extract it. At 11.30 P.M., on retiring to rest, I swallowed as much of the drugs as I could, probably fifty out of the sixty grains used, and washed them down with the infusion. In five minutes, I felt a glow, an increased circulation, an uneasiness in the head, became restless, and the secretion of saliva began to increase. At 11.45, a quarter of an hour after taking the dose, I was perspiring freely. The salivation and perspiration continued to be profuse until my sight became blurred. At a distance of four feet, I could see my wife, but could not distinguish her eyes. On this occurring, I became a little anxious, as I thought I must have taken an overdose. I requested that Dr. Ringer might be sent for; he came about 12.15 A.M. The impaired vision still continued, but I was glad to find that it was only at a distance—near objects I could see distinctly enough. The pupils of the eyes were slightly dilated, I was informed. The pulse when first noted was 96, and got up to 104. The temperature was not taken. The depression was never very great; but a little before Dr. Ringer came, I began to shiver, more clothes were put on the bed, and some spirit and water given to me. The excessive perspiration still continued from all parts of the body. A Turkish bath, which I have frequently had, and seen others have, was nothing to it—the saliva for a time required almost constant ejection; the secretion of this from the glands in the cheeks caused a kind of collapsed feeling in them. This so affected my speech, that articulation was both difficult and indistinct. Eventually, about 1 A.M., I was sick, and vomited at first a quantity of saliva which I had swallowed. Putting my finger in my mouth, vomiting was further excited, until a portion of the jaborandi returned. The effects were now subsiding; more spirit and water were given to me, my night-shirt, soaked with perspiration, was changed. I was put into a warm blanket, and, about 1.40 A.M., I fell asleep, and slept a quiet sleep till 6 A.M. The pulse on awakening was 88—normally with me it is 80. I got up about 7.30 A.M., and although I felt squeamish all next day, I was able to attend to business as usual. When the action was at its height, on uncovering my arm, I am informed, the perspiration passed off in steam from my hand and night-shirt sleeve. The saliva collected, which was distinctly alkaline, measured sixteen ounces, in addition to which a quantity had flowed on to the pillow while I slept, as it was quite wet in the morning. I came to the conclusion, that I should not like to pass through the ordeal

again. My thanks are due to Dr. Ringer, whose presence and kindness greatly relieved my anxiety. We have undoubtedly in jaborandi a drug which produces a marked physiological action; how far it will prove useful therapeutically in cases of fever, diabetes, and other diseases, remains to be seen. A drachm dose of the last received is no doubt excessive, that is, if the whole be swallowed. The strained infusion, from what I hear, produces but little effect. M. Robin (see *London Medical Record*, December 16th) gives an account of the results of his researches in M. Gubler's wards in Paris, but no mention is made of its peculiar action upon the vision, which, so far as I am aware, has not been previously noted.

THERAPEUTIC USE OF NITRITE OF AMYL.—Dr. Fucel recommends the use of nitrite of amyl in cardialgia, in an article in the *Deutsches Archiv für Klinische Medizin*, 1874. In all cases not complicated with gastric ulcer, the inhalation of a few drops was followed by the disappearance of the pain in a few minutes. The pain, it is true, sometimes returned in half an hour or later; but it was less severe, and always ceased on another application of the remedy. The author also met with nearly equally satisfactory results in the neuralgic disorders accompanying menstruation. He also relates a case of so-called rheumatic tetanus, in which the attacks ceased after the inhalation, three times daily, of two drops of the nitrite of amyl.—*Centralblatt für die Med. Wissensch.*, No. 57, 1874.

SUBCUTANEOUS INJECTION OF STRYCHNIA IN DIPHTHERITIC PARALYSIS.—In the *Deutsches Archiv für Klinische Medizin* for 1874, Dr. Acker relates some cases of diphtheritic paralysis. In one of them, the patient, a man aged 38, had complete paralysis of both the external and internal branches of the superior laryngeal nerve. Not only was there complete loss of sensation in the upper cavity of the larynx and paralysis of the external branch supplying the crico-thyroid muscle, but also of the fibres of the internal branch which supply the thyro- and the aryteno-epiglottic and arytenoideus transversus muscles. The author believes that this peculiar affection of the superior laryngeal nerve is to be explained by the course which it takes along the middle constrictor of the pharynx, whereby the morbid process affected it by local influence, just as it produces paralysis of the nerves of the palate and oesophagus. In the case referred to, there was disturbance of co-ordination of the muscles in walking, and the paralysis of sensation and motion was most marked on the right side. The patient had also impairment of the sense of touch. The application of galvanism along the spine, along with hypodermic injection of strychnia, produced so much improvement, that Dr. Acker was led to specially examine the action of strychnia in such cases. It was used in the form of a solution containing 2 per cent.; and within four weeks 0.4 gramme (three-fifths of a grain) was injected into a man. Of the beneficial action of this treatment, Dr. Acker specially convinced himself in the case of a woman, aged 36, with complete paraplegia.—*Centralblatt für die Med. Wissensch.*, p. 57, 1874.

THE ACTIVE PRINCIPLE OF SENNA.—From several theses on senna, laid before the University of Dorpat, it appears that frequently repeated experiments show that, when an infusion of senna is evaporated in an open vessel to the consistence of an extract, that extract has very little power. If this extract be redissolved in a large quantity of water and re-evaporated, an inert extract is obtained. Alkalies alter the purgative principle very rapidly at boiling point. An infusion of senna in lime-water at boiling point, afterwards deprived of its lime by carbonic acid, gives an inert liquid. An infusion of senna, with caustic potash added at the boiling point, subsequently neutralised by an acid, is also inert. The mineral acids are less energetic in their action, and the vegetable acids seem to exercise a very feeble influence. Experiments also demonstrate that the active principle of senna is insoluble in concentrated alcohol, for the alcoholic extract has no purgative action; it dissolves very readily in cold water. Senna, treated with alcohol, loses its taste and smell, but retains its action. This senna, exhausted by alcohol, ought to be in general use, for an infusion of it can be readily administered to children, who take it without repugnance.—*Journal de Chimie et de Pharmacie*, 1874.

MIDWIFERY.

ON PULSELESSNESS IN THE CHILD DURING EXTRACTION OF THE FEET.—In two cases related by Dohrn in the *Archiv für Gynäkologie*, vol. vi, 1874, of breech-presentation in a narrow pelvis, the heart's action ceased suddenly as soon as the head entered the pelvis. After delivery, however, the children revived; the respiratory movements first appearing, then the heart's action. Dohrn believes that this arrest

of the action of the heart is not due to asphyxia, but to pressure on the brain and irritation of the vagus nerve; and he considers that its occurrence is an indication for hastening the process of delivery.

CO-DEVELOPMENT OF INTRA- AND EXTRA-UTERINE PREGNANCY.—Dr. John T. Hodgson reports (*St. Louis Medical and Surgical Journal*, August 1874) the case of a healthy female, æt. 27, in whom the early symptoms of pregnancy were attended by the development of a sensitive tumour within the pelvis, and to the left of the uterus; the tumour enlarged at the same time with the latter. For two months she had great pain in the pelvic region, with nausea and vomiting, and grew very weak. At the end of that time both the uterus and tumour had risen out of the pelvis, and the outline of the right enlargement could be distinctly traced as continuous with the neck of the uterus, while the tumour to the left, though closely pressed against the other, was distinct. It then ceased to enlarge, and gradually diminished in size, but remained tender to pressure, and in a month or two presented some irregularities in form, that had not before been observed. At the proper period, the woman was delivered of a healthy living child, the tumour having decreased until it was no larger than a lemon. A year later, it was about the same size, somewhat irregular, a little sensitive to touch, moving freely with the uterus, lying higher in the pelvis than that organ, and pushing it to the right. The case was believed to be one of tubal pregnancy, in which the sac burst about the fifth month without much hæmorrhage; the fœtus died, and a limited peritonitis occurred.

REPORTS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, JANUARY 19TH, 1875.

GEORGE D. POLLOCK, F.R.C.S., President, in the Chair.

President's Address.—In taking the chair for the first time, the new PRESIDENT made a brief address to the Fellows, of whom there was a good muster. He commenced by thanking all for the honour done to him in electing him to follow his old friend Sir William Jenner. It would be vanity upon his part to say that the honour was not highly appreciated, for the Pathological Society of London was one of the most honourable in this or any other country. Its growth was extraordinary, and its work most useful. Its *Transactions* formed a storehouse for the most distant lands. Twenty-five years ago, he had been a Honorary Secretary of the Society, and some years of office had made him appreciate the amount of instruction afforded thereby. An old President (Dr. Latham) once declared that he little knew how much he had to learn, and how pathology had advanced, till he took office. If the Presidentship of this Society carried with it so much honour and so much instruction, it might not be out of place to ask the Society to listen to him upon one point. It was in reference to the tenure of office by the President. By referring to it now, ample time would be allowed for consideration before the next election. The rules of the Royal Medical and Chirurgical Society had been adopted in 1840, when London contained but two millions of inhabitants, and but 4,560 medical men; now, the population exceeded three and a-half millions, and the medical men were 5,974. There was not only a large increase of practitioners, but also of students. With the increase of all things medical, some new regulations might be rendered desirable; and, as the members of the Pathological Society had increased greatly in number since the Society was first established, at which time the President need not be frequently changed, there were more seniors eligible for election, and a President might be oftener elected with advantage. Of the original members, but eight had served the office of President; and of those elected since, but a very small proportion had served that office, while there was a large number most eligible. The Society had become very popular, and many of those who once held aloof had subsequently joined; of these, some would fill the office well; but by the present arrangements they could not become eligible till past the prime of their energies. The advance of knowledge in many departments pointed to the value of this Society, as might be seen in the difference betwixt the knowledge of cancer in John Hunter's day and that displayed in the recent discussion. Still, we were in the dark as to the cure and prevention of that terrible malady. If annual election were adopted, many might be found who would serve the office well, and good would come of it. In suggesting, at the earliest opportunity, the annual election of President, he had no object in view but the interests of the Society.

Papilloma of the Tongue.—MR. WAGSTAFFE exhibited two specimens.

The first occurred in a child, three years of age. At six months old, the growth on the tongue was seen. It grew, and interfered with respiration and deglutition. It was about an inch long when removed. The object of pathological interest in this case was the fact that an old naevus was at the bottom of the papillomatous growth, and blood-spaces were found underneath the growth upon the surface. The second case was of greater pathological interest, due chiefly to the doubtful nature of the case. It might be questioned how far it was a papillomatous or an epitheliomatous growth. The patient was fifty years of age, and nearly the whole tongue was involved. Twenty-three years had elapsed since its first appearance. There was a suspicion of syphilis. The patient was first seen by Mr. Hutchinson six years ago. Now, the growth presented a cauliflower appearance, with a number of warts consisting of hypertrophy of the epithelium. The growth was removed by the galvano-cautery. Section showed hypertrophy of the epithelium, with a large number of "birds' nests"; underneath there was hypertrophy of the connective tissue. From the slow progress it made, he preferred to call it papilloma. There had been no recurrence.—Mr. HULKE thought that birds' nests went for little.—Mr. WAGSTAFFE replied that he thought the birds' nests of little importance, but he regarded central cells as of different omen.—Mr. FAIRLIE CLARKE doubted if the second case could be regarded as papilloma; it had gone beyond that, and become epitheliomatous. Papilloma was an innocent growth. The clinical history indicated a large operation, different from that for mere warts. Whatever the early history might have been, the growth was epitheliomatous.—Mr. H. MORRIS thought two growths might possibly be present. He asked if the dorsum had long ago possessed a white harsh growth.—Mr. WAGSTAFFE answered that the surface was much fissured. At the commencement, there was a covering of thickened epithelium. The glands were enlarged at one time; but, after the operation, they had subsided.

Congenital Dislocation of Femur.—Mr. SYDNEY JONES brought forward a case of congenital dislocation of both hips, in a girl, aged 17, who had been treated for spinal disease. The history was, that the mother had a fall during the intrauterine existence of the child, but at what period was not exactly known. There was no damage done to the child in labour. The trochanters were carried up to the ilium. The thighs were inverted; the person was knock-kneed, and the feet were thrown out, or, in other words, splay-footed. The heads of the thigh-bones could be pulled down for a short time only. There was no pain and but little inconvenience, the rolling gait being the most marked matter.—Mr. HOWARD MARSH said that several different pathological conditions were classed under the heading of congenital dislocation of the hips. No satisfactory explanation of the phenomenon had yet been given. He had seen a case lately where this affection was apparently hereditary. The person could dislocate her hips at will. Her daughter had the same lesion.—Mr. MORRANT BAKER had a case lately at the Evelina Hospital, in a boy aged 3. The case would be published.—Mr. NUNN alluded to Charcot's cases, where there was coexisting nervous disease.—Mr. H. MARSH doubted if cases ever occurred from nervous disease.—A desultory discussion followed, in which Mr. S. JONES remarked that a projection of the sacrum backward was found.

Lymphangioma secreting Chyle.—Mr. S. JONES exhibited a living specimen of this morbid condition. The patient was thirty-one years of age. There was no history of syphilis, and the man had never been out of England. There had been no injury to the limb. Seven years ago, the right limb had begun to swell. The swellings resembled varicose veins. They were of a pink colour, were emptied by pressure, but filled again. There was a discharge of milky fluid. Only recently had the discharge become copious. It had some smell. The skin was tuberculated, and there was a prominence on the shin. When there was no discharge, lumps were to be felt. The limb was enlarged. It was worst when hanging down. The man had lost flesh. He had had curious inflammations of the thigh and leg. Swellings appeared like distended lymphatics, with a pink network following, merging into general redness, and passing ultimately into desquamation. At one time, the temperature was 102 deg. Fahr. In these attacks, the vessels in the back of the thigh were like varicose veins. They then burst, and a chylous fluid flowed, with great relief to the symptoms. Great hunger accompanied this process. The treatment consisted of elastic pressure, with complete rest, and ergot internally. This had done him much good. The fluid soon coagulated and formed a firm clot. The microscopical characters were those of milk, with some corpuscles. A rich cream formed up in the fluid, and the ash was alkaline. Dr. DAY related a similar case in a boy, which he had recorded in the *Clinical Transactions*. When first seen in 1863, this boy was two and a-half years old, and the enlargement was below the knee. Gradually, it spread upwards, and the knee-joint of the affected limb was larger than that of the sound one. The swelling was increased by exercise, and

then the limb felt brawny. A surgeon who then saw the boy thought there was obstruction of nearly the whole of the femoral vein. In time, the prepuce became involved, and ultimately a small testicle formed upon it, which burst one night in bed, and a copious discharge followed. The ruptured vesicle was supposed to be a varicose lymphatic. The presence of chyle-corpuscles in the fluid suggested the idea that the thoracic duct was involved. The affected limb was both stronger and longer than the unaffected limb. Rest always lessened the size of the limb, while action led to swelling of the lymphatics. Crutches did much good.—Mr. MORRANT BAKER said the case had once been in St. Bartholomew's Hospital, but had been lost sight of. He inquired into the characters of the fluid, remarking that, if there were obstruction in the thoracic duct, there would probably be other symptoms.—Dr. FAYRER said that these cases were common in India, much more so once than now. The disease was not necessarily elephantiasis, but was often so. Mr. LEWIS had recently found the urine to be chylous, and that a peculiar filaria existed in the blood. A distended condition of the lymphatics was common with elephantiasis. In one case, it occurred from cutting the femoral vein.—Mr. WAGSTAFFE had also a case of elephantiasis, where there was hypertrophy of the skin, with enlargement of the lymphatic vessels. There was much fluid lost. In this case, syphilis was probably present. The other limb was also affected. The cause was probably an abscess in the groin, where there had been a large hydatid, and two pints of fluid came away. The fluid was albuminous. The urine was albuminous, but not chylous.—Mr. S. JONES said the urine was not chylous in his case.—Mr. MARCUS BECK said the patient had been in University College Hospital. The diagnosis was enlargement of the lymphatics as far as the thoracic duct. Rest, etc., were enjoined, but little good came of the treatment.—The case was referred to a special committee, consisting of Mr. S. Jones, Drs. Fayrer, George Harley, and Burdon Sanderson.

Hypertrophy of the Knee.—Mr. S. JONES related a case of hypertrophy of the knee-joint, following disease and suppuration of five years' standing. There was a certain amount of lameness. The limb was one inch and a half longer than its fellow, from growth in the femur and tibia. After resection of the knee, the limb is often of fair length from such hypertrophic growth.

CLINICAL SOCIETY OF LONDON.

FRIDAY, JANUARY 22ND, 1875.

GEORGE W. CALLENDER, F.R.C.S., F.R.S., Vice-President, in the Chair.

Periostitis relieved by Incision.—Mr. PRESCOTT HEWITT exhibited a man who had been under his care with periostitis of the humerus. The patient was a railway porter, aged 46, who had always enjoyed good health. As a young man, he had contracted a chancre, but this was not followed by secondary symptoms. He had never had any accident. For some time previous to his coming under observation, he had suffered from pain in the right arm, which he had attributed to rheumatism; but he had had no symptoms of rheumatism in any other part of the body. Six years ago, he began to suffer from intense pain in the right arm, especially at night, and this was followed by the appearance of a swelling on the outer side of the middle of the arm. This had continued for two years, when he came under the care of Mr. Hewitt. There was then found to be a mass as large as the fist, and as hard as ivory, spreading along the bone from the point of insertion of the deltoid muscle, firmly connected with the bone, from which it could not be moved. The diagnosis was made that the case was one of periostitis, with effusion of lymph spreading into the sheath of the deltoid muscle. He was ordered iodide of potassium—thirty grains three times a day—but without any effect, beyond the fact that the pain appeared to be somewhat lessened occasionally, and then returned with renewed vigour. After a few months of this treatment, as no relief was afforded, he was admitted into St. George's Hospital; and, under the influence of chloroform, a free incision was made through the whole thickness of the tumour down to the bone. The mass was excessively hard, so that the knife was quite blunted by the operation; in fact, the tissue cut through resembled a piece of dense fibro-cartilage. From this time, the pain entirely disappeared, and the swelling gradually decreased. There was now only a little lateral thickening about the bone; the movements of the shoulder-joint were, however, impaired, and there was a certain amount of fibrous ankylosis of the elbow-joint. Some mobility which was apparently left at the shoulder was due to the motion of the scapula upon the trunk. The patient was able to follow his occupation as porter, and could lift as much as a hundredweight. He had remained entirely free from pain, and had gained flesh.

Mr. CALLENDER remarked, that the Society was much indebted to—

the late President for bringing forward this case. It had been laid down as a principle by the late Mr. Stanley, that in similar cases of chronic enlargement of bone, accompanied by severe pain, much relief was given by cutting down upon and dividing the periosteum; the effect of that operation would lead one to suppose that the pain was simply due to tension of the periosteum. As regarded a second point, the growth of exostoses, Mr. Callender had found that a very great number grew from the ridges into which the muscles were inserted, and he had thought they might have their beginnings in some irritation of the muscle, an overstrain for example. Had Mr. Hewett in his mind any fixed idea of the cause of the fixture of the joints? Would he think any forcible manipulation of the joints under chloroform likely to benefit the patient?—Mr. T. HOLMES had been very much struck with this case, before Mr. Hewett's successful operation, as a problem in diagnosis. A very eminent surgeon of London had previously seen the case, and thought it one of malignant disease, and advised amputation at the shoulder. Mr. Holmes had seen three cases of the same disease in the femur in children, in which the question of amputation at the hip-joint had been discussed. And a case was recorded in the *Transactions of the Pathological Society*, in which a bone similarly affected was excised. A good lesson should be learnt, therefore, with regard to these wide-spreading periosteal tumours, not to be in too great a hurry to amputate, but to wait, and to be ready to do so only as a last resource.—Dr. BUZZARD asked, what was considered a large dose of iodide of potassium; because he had found that, whereas doses of five and ten grains often did no good, with doses of twenty, thirty, or forty grains every four hours, syphilitic patients had been benefited directly, and those who had not slept for months often enjoyed a good night's rest at once.—Mr. BARWELL remarked, that the tumour was developed at the insertion of the deltoid, and had seemed to extend into that muscle, so that it probably began in a wrench-injury to the muscle. He had seen a young gentleman who had strained his knee in the hunting-field, and had ruptured the ligamentum patellæ, not far from the tibia, and who recovered sufficiently to go about and follow his avocation. Fifteen months afterwards, he had a commencing large exostosis from the same place, which had continued to grow until he was lost sight of on going to India fifteen months ago. In Mr. Hewett's case, the tumour had spread so far that Mr. Barwell thought it was not altogether due to merely local influence; and it must be recollected that the man had had primary, if not secondary, symptoms years ago.—Mr. CALLENDER had lately seen a young gentleman who had, eighteen months previously, sprained his arm; the whole arm was swollen, cedematous, and was evidently the seat of diffused cellulitis. In Mr. Hewett's case, perhaps, the same kind of chronic inflammation had extended to the joints, and produced the partial ankylosis. Mr. Callender would have thought seriously of his case, but the gentleman had had the same trouble previously, and had recovered. Iodide of potassium was ordered for him, and in a few weeks he was well.—Mr. PRESCOTT HEWETT had broken down several ankylosed elbow-joints, but had never known one to succeed; such was his experience as far as the elbow-joint was concerned. All such cases became stiff again: why, he could not say. Such was the fact. He had not had the same experience with the shoulder-joint. A young officer, who had had thickening of the shoulder, which had been broken down and then became stiff again, could fairly wield his sword and go through the other exercises, simply from the mobility acquired by the scapula. The patient exhibited to the meeting had taken thirty grains of iodide of potassium three times a day, and that was a fair dose. Mr. Hewett had seen the greatest benefit arise from such a dose. A patient at St. George's Hospital, who had had secondaries, had violent delirium. Mr. Hewett supposed it to be due to syphilitic periostitis of the skull, and gave thirty grains of the iodide thrice daily, with the effect that, in two or three days, the man was quite well.

Subperiosteal Excision of the Os Calcis.—Mr. HOLMES brought forward a case, which had been performed as nearly as possible after the method prescribed by M. Ollier. The patient was a boy, aged 14, and the operation was performed on January 31st, 1875, by a curved incision carried down the external inferior border of the calcaneum and along the external margin of the os calcis. The only tendon which was divided was the tendo Achillis, which was turned away from the bone along with the periosteum. The bone was removed, perfectly free from soft structures, except on the inner side, where some of the periosteum was necessarily taken away with the bone. The case was a very favourable one for the operation; but a good deal of difficulty was experienced in performing the excision, and the operation was followed by great inflammatory reaction. Ultimately, though the boy recovered well, the ankle-joint and the transverse tarsal joint, as far as could be ascertained, were found to be ankylosed; and the use of the foot was not so good as in other cases which had been under the care of

the author, in which no care had been taken to preserve the periosteum. The patient had been exhibited to the Society at the last meeting. Mr. Holmes remarked that in a former case, in which he had followed M. Ollier's rules in the subperiosteal excision of the elbow, he had found the result inferior to that obtained by the ordinary method in the most successful cases.

Mr. BARWELL recalled to mind the fact that a paper had been read before the Society last year by Mr. Croft on a very successful case of subperiosteal excision of the hip-joint, done according to the plan of Dr. Sayre of New York. Dr. Sayre, having cut down to the bone, separated the periosteum with a kind of oyster-knife, and then excised the head of the bone. Mr. Barwell had had a case in hospital in which Dr. Sayre, who was present, had by request finished the operation. In another case of excision of the knee, done according to the same method, there was ankylosis before the external wounds were healed, which was, perhaps, attributable to the subperiosteal method. In taking out sequestra of bone, it was best to cut straight down to the bone through all the tissues, and peel off the periosteum with the soft parts attached to it; not to denude the periosteum from both sides, which was likely to produce failure from death of the membrane. Mr. Holmes would probably have had greater success in his case without the subperiosteal method; for, in excision of the os calcis according to the usual method, the tendo Achillis and other muscles subsequently regained their action. When bone was removed from a large cavity, one could not expect that bone should be reformed there at once. Pus was first poured out, and filled the cavity. He (the speaker) considered that the removal of large pieces of bone by the subperiosteal method was sure to be unsuccessful: the patient ran in danger from the collection of pus in the large cavity; and, although it might be plugged with lint, yet, as had been shown, the daily disturbance of the surface of granulations in a wound, as by the removal of the lint, was rife with dangers to the patient.—Mr. HAWARD had had under his care in 1871 a girl whose elbow he had excised subperiosteally. The disease ran a long way up the humerus, so that a large piece of the bone had to be removed. It was a tedious case for operation, but he had managed to leave a large portion of the periosteum upon the removal of the bone from beneath it. There was no great subsequent inflammation, considering the injury done in the operation. At present, the child could use the arm well, and had good motion of the elbow. The period of recovery had, however, been a protracted one, much longer than would have been required had the operation been done by the ordinary method. In some of these cases, excess of bone had been thrown out, and loss of mobility had resulted therefrom. The bloodless method was of great advantage to the operator, as he could then hit the joint at once.—Mr. CALLENDER would have two objections to the subperiosteal method for operation in such cases. Firstly, the disease was due to caries, and therefore the periosteum had undergone grave changes. Secondly, there was a very small piece of periosteum which could be removed with the articular end of the bone, except when the shaft was diseased. In removal of sequestra, he always lifted up together the skin, tendons, periosteum, etc., from the bone. As regards the bloodless method, which was a great advance in surgery, it had been said that it had not been adopted before Eschschütz introduced his plan; but such was not the case. Mr. Hilton, at Guy's, had been accustomed to use a similar procedure; he used to bandage and elevate the limbs of bloodless patients for an hour or so before their amputation.—Mr. HOLMES would think the great objection to Dr. Sayre's method at the hip-joint was the fact that the operation had to be begun low down—below the insertion of the gluteus minimus. At the elbow, there was a good deal of periosteum on the olecranon; and the bone formed by that periosteum interfered considerably with the proper straightening of the elbow after the operation. In Ollier's operation, the incision was carried down to the bone at once; and the periosteum was reflected from the bone, together with all the other tissues covering it.

Optic Neuritis, with complete Loss of Vision under Treatment.—Dr. THOROWGOOD read notes of the case. Kate G., aged 12, was admitted into the West London Hospital October 23rd, 1875. The history, taken by Mr. Blackman, the clinical clerk, was as follows. The patient had had, five weeks previously, a pain at the lower part of the back from a blow against a desk. Liniment was used; and in a short time this pain left her. Shortly afterwards, a pain came at the back of her neck, with tenderness, swelling, and stiffness on movement. For this, she saw Dr. Thorowgood, who gave her a belladonna and mercury liniment, which she used, and the pain and stiffness went away. A week after this, she noticed a fog before her eyes, which gradually increased, till in a week vision was perfectly lost in both eyes. She was now admitted to the hospital. No sign of disease or injury of spine could be detected. She could just discern between light and shade. On October 24th, Mr. Bowater Vernon examined her eyes with the oph-

thalmoscope. The optic discs were swollen, with irregular outline; the veins engorged, and obscured in places; whole fundus oculi paler, and more yellow than normal. No hæmorrhage. The same description applied to both eyes. She was not feverish; the organs of the chest were healthy; there was no albumen in the urine. Two leeches were applied to the temples, and three grains of hydragrym cum creta given every three hours. October 28th, she was much the same; to have thirty minims of liquor hydragryi perchloridi three times daily in decoction of bark. Leeches were again applied to the temples. On November 1st, Mr. Vernon examined the eyes again. The right optic disc was much swollen; its outline was completely obscured. The fundus was ash-grey in colour. The left eye had the surface of the disc marked by apparently numerous small vessels. Under treatment with iodide of potassium, and then liquor strychnie with iron, this patient improved; and on December 23rd, 1873, was seen as out-patient, and able to read well. On January 22nd, 1875, she was seen again, and her vision, tested by Mr. Vernon with Snellen's type-board, was declared normal. The left eye was rather better than the right, which was, perhaps, not quite up to the normal range. The optic discs looked pale and anæmic. In commenting on the case, Dr. Thorowgood said that Mr. Vernon considered the case one of true optic neuritis, not a mere congestion from impeded return of blood to the sinuses. The question was, had the spinal pain any connection with the neuritis? In cases of loss of vision due to spinal disease, atrophy of the disc might be expected from the great sympathetic being involved. The present case seemed one of basilar meningitis extending to and involving the optic nerves. Meningitis might be very insidious in its progress, and might do much mischief, if not controlled by treatment. The present case showed the value of the ophthalmoscope in detecting meningitis, and so guiding to a plan of treatment by local depletion and mercurial medicines, which proved very successful.

PATHOLOGICAL SOCIETY OF DUBLIN.

SATURDAY, DECEMBER 5TH, 1874.

ROBERT McDONNELL, M.D., President, in the Chair.

Bright's Disease.—DR. QUINLAN showed the heart and kidneys of a woman who died of Bright's disease. When admitted to hospital, she was suffering from extreme anasarca of the lower limbs, and her urine was highly albuminous, numerous tube-casts being visible under the microscope. She died two days after admission. The heart was hypertrophied, and the kidneys were extensively diseased, presenting signs of recent congestion superadded to pathological changes of older date.

Extra-pericardial Creak caused by a Tongue of Lung-Substance.—DR. NIXON presented the thoracic viscera of a man, aged 64, who had suffered from renal dropsy. The urine contained blood, much albumen, and granular tube-casts. He was admitted to hospital with general bronchitic riles, increased precordial dulness, and a soft post-systolic murmur at the seat of cardiac impulse. This murmur altered in intensity from time to time, and was not audible in the axilla or posteriorly. It disappeared after exercise. Subsequently, a dry creaking sound, most audible at the end of expiration, was observed. It ceased after coughing. The necropsy revealed excessive fatty degeneration of the kidneys. But the most interesting pathological condition was the existence of a tongue of lung-tissue on the left side, which overlapped the pericardium, and clearly gave rise to the dry creaking sound by the tilting against it when filled with viscid mucus of the pericardium, with every impulse of the heart. Dr. Nixon reminded his hearers that a similar sound had been described in the same situation as being due—(1) to the stretching of bands of lymph in pleuritis from the lung to the pericardium (Addison); (2) to the pressure of a consolidated lung in tuberculous; and (3) to the existence of cavities with thick walls (Austin Flint).

Cerebro-Spinal Meningitis.—DR. BENNETT exhibited the brain and base of the skull of a seaman, a Russian Finn, who died after a very short illness in Sir P. Dun's Hospital. It appeared, that fifteen months ago, he had fallen from a height on the deck of a vessel, and had afterwards suffered from pain in his right ear. He was insensible, very delirious, with contracted pupils, pulse 72, respirations 38, and marked pulsation of the external jugular veins. There was no cardiac disease; the skin was free from eruption. After death, the brain was found congested, yellow bands of lymph lay along the superficial vessels of both cerebral hemispheres. A deposit of green lymph lay in the circle of Willis, and on the surface of the cerebellum, and there was softening of the spinal cord. The lungs showed signs of recent and extensive congestion. Both ears were minutely examined, but the parts were perfectly healthy, and in no sense could the pathological

changes be traced to traumatic causes. The case was evidently one of idiopathic or epidemic cerebro-spinal meningitis.

Aneurism of Thoracic Aorta.—DR. GORDON brought forward a remarkable specimen from the body of a man, aged 36. He had been admitted to hospital with cough, dyspnoea, high fever, and pneumonia of the upper portion of the right lung. This had been set up by irritation from the pressure of an immense aneurismal tumour, which bulged forwards beneath the right clavicle, and presented the usual signs of aneurism. There was extreme venous congestion of the upper part of the body, and a network of varicose veins covered the chest. The right radial pulse was stronger than the left. In time, the subclavicular pulsation disappeared, constant dyspnoea set in from pressure of the right bronchus, and the ringing cough of irritation of the recurrent laryngeal nerves was heard. After death, a tumour of large size was found to spring close to the aorta. When the sac was opened, that portion of it which lay under the clavicle in front, proved to be filled with firm coagula. The right cardiac auricle was very small. The superior cava was almost occluded at one point, above which this vessel was widely dilated. The inner surface of the sternum was considerably eroded. Both pneumogastrics were flattened and compressed.

SURGICAL SOCIETY OF IRELAND.

FRIDAY, DECEMBER 4, 1874.

JOLIFFE TUFNELL, Esq., President, in the Chair.

President's Address.—The President delivered an address which was eminently practical in its scope. He gave an account of the origin of the Society forty-three years ago, and described at some length the duties of its various officers, and the principles on which it was worked. The concluding portion of the address contained a fitting allusion to the recent deaths of Drs. Arthur Jacob and W. Hargrave, two prominent members of the Society.

Elephantiasis Arabum.—DR. WHEELER exhibited the right leg of a woman, aged 30, which he had amputated for this disease. The morbid process began eighteen years previously, with a pain referred to the dorsum of the foot. Elephantoid fever ensued. A line of ulceration occurred at the ankle-joint, and again below the knee, after which the disease affected the leg without extending into the thigh.

Cancer of Male Breast.—DR. MAPOTHER showed a scirrhus tumour which he had removed from the breast of a man, aged 35.

Chronic Synovitis of Knee-joint: Amputation.—DR. WHEELER showed a well-marked specimen, with a history of five years. The patient was an adult male.

Acute Tetanus.—MR. H. G. CROLY, detailed a case of very acute traumatic (?) tetanus, which terminated fatally within thirty-eight hours. A woman, aged 30, suffered from a small painful ulcer on the inner malleolus of the right ankle; this was the only evidence of trauma. Tetanus, trismus, opisthotonos, rapidly followed each other, having been ushered in by yawning and stretching of the limbs. Ether failed to alleviate her sufferings, and she sank rapidly. Mr. Croly enumerated fourteen cases of tetanus which had come under his own observation. From a consideration of these, he held that all cases of acute tetanus are fatal. He alluded to the prophylactic treatment of tetanus, and gave the formula of Mr. Peile's "Antitetanic Pills", as follows: Hepatic aloes, twelve parts; antimonial powder, twelve parts; opium, three parts; syrup, to make twelve pills. He concluded by speaking of the pathology of the affection.—DR. McDONNELL, as a pupil of Mr. Peile, believed that each of his pills contained a quarter of a grain of calomel. Mr. Peile used to say that tetanus never followed a lacerated wound if the antitetanic pills were administered.—MR. STAPLETON could not endorse Mr. Peile's opinion. He spoke of the prominent part played by the irritation of a nerve in the etiology of tetanus.—DR. MACNAMARA laid stress on the influence of atmospheric conditions in causing the disease. As regarded treatment, he relied especially on ice. Chloroform seemed to do harm in one case.—MR. CORLEY mentioned a fatal case after amputation through the thigh, and referred to the anticipations often indulged in by patients as to the approach of tetanus.—DR. BARTON alluded to the occurrence of yawning in a patient of his, twenty-four hours before trismus set in. He thought highly of chloral and hypodermic injections of morphia as remedies.—MR. O'LEARY narrated a case of trismus after a burn, in which the initial symptom was yawning; spasm of the larynx killed the patient in forty hours.—DR. H. KENNEDY dwelt on the pathology of tetanus, and quoted Dr. Lockhart Clarke's views as to its arising from a spinal lesion.—MR. E. HAMILTON spoke of atmospheric influences, and the cure for tetanus practised by the Tonga islanders, namely, counterirritation by passing a hook through the penis.

BRITISH MEDICAL ASSOCIATION:
SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, JANUARY 30TH, 1875.

VIVISECTION.

WE have already intimated that, owing to recent circumstances, notably the prosecution of Dr. Magnan at Norwich, we thought it desirable to collect the opinions of eminent members of the profession on the subject of vivisection, and its utility as a means of ascertaining facts likely to be of service in advancing the healing art. We would call the attention of our readers to the two communications we have already published (the JOURNAL of January 9th, page 56, and January 16th, page 90) as specimens of numerous replies of a similar nature which have been sent us. In these it will be seen that it is claimed for experiments on living animals, that they have been the means of discovering many of the fundamental facts of physiology, and that the practical application of these facts has greatly advanced our knowledge of the nature and treatment of disease. We believe that the opponents of vivisection do not deny that great scientific truths have been arrived at in this way, but they question very decidedly whether the ends justify the means. As it is eminently desirable that this subject should be discussed apart from mere sentiment or prejudice, we will endeavour to state the points at issue, and weigh the arguments advanced by either side.

There can be no doubt that the very term "vivisection" is of itself sufficient to excite in sensitive minds feelings of repulsion. The sight of operations on living beings for what purpose soever is, to those unaccustomed to them, anything but agreeable. Few, if any, of our medical readers witnessed the first surgical operation at which they attended without experiencing a distressing sickening sensation; and, had they consulted their feelings only, would much rather have retired from the spectacle. This feeling arises naturally in all, even when they are aware that the patient is quite unconscious of pain. If to the sight of the operation itself there be added the knowledge that the patient is suffering excruciating agony, when the necessities of the case forbid the administration of an anæsthetic, the feelings of a sensitive spectator can be better imagined than described. It is not until the emotional has been conquered by the intellectual, that we can look on calmly, or assist at the work of the operating theatre; and there are many who never acquire this ascendancy over their emotional nature. In general, the contemplation of the end aimed at absorbs the mind, and what before were horrible and distressing sights, come to be regarded as skilful and kind means of relieving a patient from suffering of a more grievous character. In the surgeon who performs vivisection experiments on human beings, we have an example of one who performs acts, viewed in themselves, of a repulsive nature, and who, nevertheless, is not in general regarded as guilty of cruelty, or devoid of regard for the feelings of others or sympathy with human suffering. If we contrast with this the picture of a carman inflicting heavy blows and kicks on the legs and sides of a groaning horse, perspiring at every pore, and straining every muscle in its ineffectual attempts to move a heavy load for which it is utterly unfit, the sickening sensations give place in the mind of the spectator to feelings of indignation against the cruel brute who can so

unmercifully treat a dumb creature unable to protect itself or declare its wrongs. We rejoice in the existence of a Society with vigilant eyes to bring to judgment all who commit acts so unnatural and inhuman. In the two pictures we have drawn, it is easy to recognise an important distinction—the distinction between cruelty and the infliction of pain. The infliction of pain, with a benevolent motive, is not cruelty; the infliction of pain, for its own sake, or without necessity, is cruelty, and of this there may be various grades. To which of these two classes does vivisection belong, is the question at issue.

In order to clear away any misconceptions that may exist as to the nature of vivisection and its objects, it will be well to enumerate what things are included under this term. Experiments on living animals have been and are performed under such circumstances as the following. A surgeon, conceiving that a certain operation may enable him to cure certain diseases which have baffled other treatment, performs the operation on a living animal, in order to ascertain whether he may with safety perform it on a patient rather than run the risk of sacrificing the patient's life in the first instance. The physiologist performs experiments on living animals in order to ascertain the functions of certain structures, and the laws regulating vital action not otherwise capable of being ascertained with certainty. The pathologist, wishing to ascertain the exact cause and nature of some disease, establishes the disease in some of the lower animals, and studies its progress with a care and exactitude which it is utterly impossible for him to employ in the case of a human being. The pharmacologist and the toxicologist endeavour, by experiments on the lower animals, to ascertain the action of drugs and poisons on the animal economy, with a view to the treatment of disease and the detection of crime. Experiments are further made on living animals for the purpose of demonstrating some great fact to those whose acquaintance with such facts is a matter of public consequence. These, or similar, comprise all the occasions on which experiments are made on living animals by scientific men and members of our profession. Those who so experiment urge that there are great numbers of problems the solution of which would, in the end, confer benefits on mankind; and that, as the questions that have to be answered relate to life in health and disease, and can only be determined by experiments on living beings, it is better to experiment on animals, than to allow human beings to go on enduring suffering and misery which a more extended knowledge may succeed in averting or relieving. It is the old principle, *fiat experimentum*. But the question arises, Are rabbits and dogs to be regarded, in this relation, as *corpora sensibilia*? Have we any right to take dumb creatures which confide in us, and, without their consent, make use of them for our own benefit and for advancing our knowledge? We will not here stay to discuss the abstract right of man over the lower animals, but will content ourselves with asking whether the use of animals for scientific experiments is consistent or not with the use to which mankind in general consider themselves justified in putting the lower animals. None but vegetarians question our right to sacrifice thousands of animals every day to supply ourselves with what we consider necessary elements of our food. If we could only, with justice, use for our own needs such animals as would consent to be so treated, we should, if there were any means of ascertaining this fact, find ourselves entirely deprived of animal food, for the principle of conservation of life is as strong among the lower animals as among human beings. We consider our consciences satisfied if we put these animals to death without inflicting unnecessary pain on them. That we do not entirely succeed in this is a fact which the sights to be seen at the shambles prove to a demonstration. We, therefore, as these facts show, exercise an authority and a right over the lives of the lower animals for our own benefit.

Next, we may inquire whether we ever feel justified in inflicting pain on them. That we do on many occasions is likewise easily proved, and we give one or two instances. The process of training animals from

their natural habits for our own needs, frequently entails an immense amount of suffering on them. We perform various painful vivisection experiments on them—witness castration. We lop off sheep's tails, and otherwise train animals to suit our own convenience and tastes, and not for the sake of any benefit to the animal-themselves. We are not accustomed to hear charges of cruelty brought against those who do these things. Then, on the other hand, things are done every day by sportsmen, some of whom are sensitive, which, as far as the infliction of pain on the lower animals is concerned, cast into the shade the doings of all vivisectioners put together for a whole year. The sensitive sportsmen who object to vivisection on the ground of cruelty, are open to an *argumentum ad hominem*. Ladies, likewise, who oppose vivisection, would do well to inquire whether they are justified in wearing the skins of animals, almost every one of which might tell a harrowing tale of its former owner, trapped and bruised, and dying miserably after long hours of suffering, cold, and starvation. The uses for which the skins are required cause the animals to suffer in this manner. We apprehend, if a charge of cruelty is to be preferred, the wearers of furs are in some degree chargeable as art and part. We have now brought forward several instances—and we have not by any means exhausted them—in which we take the lives of animals, or inflict pain on them, for our own purposes.

Let us now take the cases of generally accepted justifiable treatment of the lower animals as a standard by which to try the justifiableness of experiments on the lower animals for scientific purposes.

We will take the case of the surgeon who, before the treatment of aneurism by ligature was known, having a patient suffering from an aneurism threatening every day to burst and end fatally, is anxious to know whether he may place a ligature on the artery without endangering the vitality of the part beyond. To determine this, he has recourse to experiments on the lower animals rather than on his patient. Is he justified in doing so?

In the next place, let us suppose a physiologist or physician who, plainly perceiving that a knowledge of the exact cause of the sounds of the heart is the key to the determination of the nature of diseases of the heart and their treatment, proceeds to experiment on living animals in order to acquire the necessary knowledge. Is he justified in doing so?

Further, let us take the case of an experimental pathologist, who, desirous of ascertaining the exact nature of the morbid poison of some infectious disease which baffles medical skill and slays its thousands every year, endeavours to establish the disease in the lower animals, and, by the study of their sufferings, perhaps succeed in benefiting the whole human race. Is he justified in doing so?

We will put another case. A pharmacologist or toxicologist, thinking over the thousands who perish by the bites of venomous snakes every year in our colonies, is of opinion that, if the real nature and exact action of the poison were known, possibly an antidote might be discovered. He therefore poisons numbers of rabbits and cats and dogs, and carefully studies the symptoms manifested, and makes experiments on them with remedies. Is he justified in thus endeavouring to benefit man by the sufferings of animals?

Lastly, we instance the case of a physician who thinks that, by his observations and experiments, he has discovered in some article of food or luxury largely consumed a fertile source of special forms of nervous disease, and, anxious that his researches should be widely known, and his facts be freely criticised, demonstrates the basis of his assertions by an experiment on a living animal in the presence of a body of professional men to whom the knowledge so acquired might be extremely valuable. Is he justified in doing so, or is he guilty of cruelty to animals?

These are examples, not altogether hypothetical, of the occasions and purposes for which experiments are performed on living animals. Judged by the standard we have set up, we apprehend that the use of

the lower animals by scientific men for the purposes of advancing human knowledge and mitigating human suffering, will stand favourable comparison with the employment of them to satisfy our appetites, or minister to our bodily comfort and convenience. It may, however, be said, that we have put the strongest cases, and that the samples we have given of vivisection experiments are far superior to the bulk. What we have done is to put cases, the practical bearings of which can be readily appreciated by all. If the principle be once conceded that, in the instances brought forward, those who perform such experiments are justified in doing so, the discussion of the justifiableness of this and that experiment is a matter of secondary importance. The direct practical good which the solution of any one vital problem by vivisection is to effect, is not capable of being made equally clear to all. Great discoveries are not made every day; the building of the edifice of knowledge is a process of evolution, and the materials are only slowly accumulated by the labours of thousands of individual workers. In themselves, many scientific facts may, to the uninitiated, appear trifling; but it is well known that many of our greatest triumphs in physical and biological science have sprung from such so-called trifles. From what we know of the motives which actuate the experimenters on animals, both at home and abroad, we are sure that it is the desire to solve some important question in physiology and medicine that leads to this, the only kind of research which is capable of determining the questions. By their united efforts, medicine has been steadily advancing, and the general good has been promoted. We think it may be safely left to a body of educated men to decide for themselves on what occasions experiments on living animals are necessary.

We have purposely avoided introducing the question of anæsthetics into the discussion, but have stated the points at issue as if the subject were being argued fifty years ago. Chloroform disposes of a number of difficulties. Vivisection of an animal rendered unconscious by chloroform need excite no scruples, if we admit the right to take the lives of animals for our own needs. There is no question of pain, and it comes practically to dissecting a dead animal. Chloroform, or some anæsthetic, ought to be given to every animal used for experiment, if it can be administered without frustrating the objects for which the experiment is made. We think that every experimenter is morally bound to abolish suffering in the subject of his experiment when he can do so without prejudice to his inquiry; otherwise, by the infliction of unnecessary pain, he is guilty of cruelty. This, we believe, vivisectioners themselves are quite ready to admit, and endeavour to carry out. The use of anæsthetics has an important bearing on the question of how far teachers are justified in experimenting on living animals, for the purpose of demonstrating to a class of students facts already sufficiently well established. It is eminently desirable in teaching a science largely founded on experiment, to illustrate lectures by practical experiments so far as possible, otherwise the real instruction given is of extremely small value. To teach chemistry or physics without experiments, would be to talk in an unknown tongue. Physiology, in many respects, stands in the same position, and the importance of physiology to medical men can hardly be overestimated. Chemistry and physics differ from physiology in this respect, that their experiments do not involve the life or feelings of the lower animals. But, with the aid of chloroform, a physiological experiment may be brought, as far as suffering is concerned, into the condition of an experiment on lifeless matter.

Under such circumstances, there can be no real grounds of objection to physiological experiments. It is only when the experiments involve suffering that a difference of opinion may be entertained as to their justifiableness. We think they ought not to be performed, unless it can be distinctly shown that instruction cannot otherwise be communicated in matters of fundamental importance. We think that, if the objects for which experiments on animals are undertaken are fairly considered,

there is no more reason for accusing the operators of cruelty, than there is for accusing of inhumanity a surgeon who inflicts pain for a benevolent motive.

THE KING AND QUEEN'S COLLEGE OF PHYSICIANS: THE NEW CHARTER QUESTION.

IN the JOURNAL for December 12th, we called attention to the discussion which had arisen in consequence of the publication of a dissent from the provisions of the proposed supplemental charter for the Irish College of Physicians. We had, on July 11th, called attention to the memorial which the College had presented to Her Majesty's Government, praying for the new powers sought by the College. We have thus kept our readers (and among them are many—probably a large proportion of the—licentiates of the College) fully informed of the nature of the proposed changes; and we cannot see how these changes would in any way injuriously affect the licentiates or the public. We may repeat that the proposed changes sought for by the College are—

1. Power to vote by ballot at all College meetings.
2. A recognition by name of all the present existing fellows, as there seems to be a doubt of the legality of the election of some of them.
3. Power to institute an order of members.
4. Power to appoint additional examiners to the censors, only four in number, who at present constitute the sole board of examiners for the College license.
5. Power to persons to resign their fellowship.

There can be no possible reason why an election at a College of Physicians should not be carried on by ballot, the system which is now recognised by the State for parliamentary and municipal elections. We had thought that vote by ballot would not have been necessary to secure independence of voting in a body of highly educated gentlemen like a College of Physicians; but, unfortunately, it has been otherwise demonstrated by the attacks of a body calling itself the Irish Catholic Union upon Dr. Hayden, an independent Roman Catholic fellow of his College, who has been held up to the public odium of his co-religionists on a charge of trying to prevent them, by means of the ballot, from gaining admission to the College. Such a charge against Dr. Hayden is as unfounded as it is unjust, and at once proves the nature of the reasons urged by the objectors against the use of the ballot at the College elections, which are as follows.

"The only attempted justification we have ever heard of this present demand for the ballot is that, by it, fellows would be free to vote for or reject candidates as they pleased, without fear of detection; but this is, in our opinion, a most unworthy motive, and it overlooks the important contrast that, while the fellow would protect himself under the shield of secret voting, the candidate, however worthy, is exposed to have his reputation stabbed in the dark by personal pique, professional jealousy, or religious animosity. The risk and injustice would be more likely to occur in a constituency so small as that of the College, than in a numerous body of electors."

We are surprised that five members of the profession could be found to make such a charge of foul play against a body of gentlemen as that contained in the above quotation. The way in which this charge has been used for the purpose of a personal attack on Dr. Hayden, proves the injudiciousness of its authors.

We cannot see how the use of the ballot at elections can injure the licentiates who may hereafter become candidates for the fellowship. It is proved by the attacks on Dr. Hayden, that the ballot is a necessary protection for the independence of voters even at a College of Physicians. It is with great regret that we have to refer to this question, especially as we hoped that the politico-religious element of discord, which has proved fatal to so many Irish institutions, had at least been excluded from the discussion of medical questions.

The only other question which could affect the licentiates is that of the introduction of a grade of members into the College constitution. We pointed out in July last the necessity of such a grade, in order to give the licentiates of the Irish College the power of raising themselves into a position similar to that enjoyed by their English and Scotch

brethren. The want of this opportunity has prevented Irish licentiates from obtaining appointments open to English and Scotch physicians.

The following very remarkable paragraph occurs in the document put forward by the dissentients.

"To the institution of the proposed new grade, that of membership of the College, we object, on behalf of 1,200 licentiates of the College, whose fees constitute the chief income of the corporation, and who are not represented upon it. A question so deeply involving the interests of the licentiates should not be dealt with behind their backs by a small body, and one in which they have no voice."

We have not yet heard that the 1,200 licentiates of the College have chosen these five dissentients to represent their views in preference to the forty-five other fellows of the College. One of the dissentients, Dr. Lyons, proposes to the College that a meeting of licentiates should be summoned by the College to consider this proposed charter. Dr. Lyons seems to forget that summoning a meeting of persons, the very large majority of whom are unable to attend, would have the appearance of paying a very empty compliment to the College licentiates. The College has, in our opinion, taken the proper course, namely, has ordered the documents connected with the proposed charter to be printed, and copies to be supplied to any licentiates who may require them. We advise licentiates, who are anxious about the matter, to write to Dr. Finny, the very courteous registrar of the College, who, no doubt, will furnish all the information which may be required, without the solemn farce of summoning a meeting of gentlemen who cannot attend.

RAILWAY SURGEONS' REPORTS.

A point of some moment to railway companies was decided on Monday last by the Court of Queen's Bench sitting *in banc*: or rather a previous decision was reaffirmed, and must now be taken to be settled, *quoad* the practice of that court. One Farquhar was suing the Great Northern Railway Company for damages consequent on personal injury. Mr. Carr Jackson had seen and examined him on the part of the company, and the plaintiff demanded to see his report to the company. On this, counsel contended that, as it was a confidential report, the plaintiff had no right to see it. Whereupon, the Lord Chief Justice Cockburn, with some warmth (to quote the *Times'* report), said, "Then, all I can say is that, in such a case, I should advise the patient not to admit the company's surgeon to see him. Why should he be allowed to see the patient, if the patient is not to be allowed to see the report he makes? If there were no negligence on the part of the company or their servants, they cannot want to see the man; and, if they have been guilty of negligence, then they have no right to intrude upon him, unless for the purpose of the discovery and the disclosure of truth for the purposes of justice. This court has upheld such an order as the present, and I think it was a sound decision. It is most desirable that a medical man, on behalf of the company, should have an opportunity of seeing the patient, in order to ascertain the nature and extent of the injury; but then, on the other hand, the party should have the corresponding advantage of knowing what report has been made to the company about him. The decision of this court was sound and wholesome, and I, for one, am prepared to adhere to it." This view was affirmed by Justices Mellor, Lush, and Archibald; and the company was, therefore, ordered to furnish the plaintiff with a copy of Mr. Carr Jackson's report.

We do not quarrel with the decision. But can it stop here? How about the company seeing the full statement of a plaintiff's own surgeon's opinions? The Lord Chief Justice incidentally observed, "It is most important that the contradictory views of the medical men in such cases should be known to each side as soon as possible before the trial. This course is best for the interests of both parties." The Chief Justice evidently assumes that the plaintiff's application for compensation discloses to the company the whole of his case. To our own knowledge, this assumption is unfounded. Facts which tell in his favour are disclosed, but those which tend to invalidate the conclusions

thus arrived at are held back. Again, there are often facts which, had they been investigated, would have told one tale; but, revealed for the first time in court, they may be incapable of true valuation. The company's surgeon may be sharp enough to detect these facts for himself; but it is not consistent with the reasons upon which the court founded its decision, that it should be left to this hazard. Further, a medical report must contain not merely facts observed, or supposed to be observed, but also inferences, arguments, and deductions drawn from these facts; in short, the scheme of the attack or of the defence. It cannot be conducive to "the purposes of justice" that the strength or weakness of the defence should be known to the attackers, when the strength or weakness of the attack is concealed from the defenders. No doubt, a frequent recurrence to the expedient of obtaining beforehand the enemy's secrets by one side only will lead to such a modification in the form of reports as to render the privilege practically nugatory.

We must now respectfully ask the Court of Queen's Bench why this rule should be made to apply to medical opinions only. A plaintiff may be entitled to compensation for injuries received; but the money-value of his injuries depends not only on their severity, but—and this is often the real question at issue—on the pecuniary loss sustained in consequence of them. This can only be gauged by the claimant's previous income and earnings. Why should not a statement of these, and the proofs of its accuracy, be submitted to the company as early "as possible before the trial"? Can any one who has listened to such cases say that this would be inconsistent with "the purposes of truth and justice"? We should be glad to see this question raised in the Court of Queen's Bench; and we hope that, when it is, the distinguished Chief Justice of that Court may be present.

As the Bench and Bar are prone to contemptuous comments on the diversity of opinion amongst doctors, we may mention that, in the course of the argument on Monday, it was stated that the Court of Exchequer has ruled that plaintiffs have no right to see the reports of the railway company's surgeons. Two wrongs do not make a right; but, while such eminent legal authorities differ as to their treatment of a simple case, doctors may feel less humiliation at differing in their diagnosis of a difficult one.

THE NAVAL MEDICAL SERVICE.

LAST week we noticed how far the performances of the Admiralty towards its medical officers have fallen short of its promises, and that therein lies a very fertile source of discontent, of which young medical men will do well to be mindful until many grievances are rectified, and matters are set on a firmer basis. In deciding on a career, they must look forward to the end of it, and not be blindly captivated by first appearances. They are not to forget that guidance is derivable from returning as well as from advancing footsteps; and, as of old the wary fox replied to the invitation of the sick lion in his lair, so they may well say:

"Quia me vestigia terrent;
Omnia te adversum spectantia, nulla retrorsum."

We say this advisedly, as we know that several who have requested permission to resign the service have been refused it; that many are devising new measures to force the Admiralty to accept their resignation from a service with which they are disgusted; while some have "run" from it, or have trusted to the cruel chances of a court-martial to set them free.

This policy of forced detention of educated men must fail in the end, as, at the best, it but keeps unzealous servants; besides which, it leads administrators into false positions, as in a recent case, where an able officer on the half-pay list, importunate in offering his resignation, was dismissed on the plea of declining to serve, and found himself thereby disqualified on offering as a candidate for another branch of Her Majesty's service which he preferred. With such instances before him, each man should carefully examine; and, while free to act, should prize greatly

that ability, and not fetter himself under such harsh restrictions, but trust to his profession and to his liberty.

We do not know what the long expected but secreted warrant may offer as inducements to join the Navy; but, as it is reported to be held back at the Treasury, we may infer that some improvements of pay and retirement are the main points in it. Unquestionably, these are prominent enough in the suggestions laid before Mr. Ward Hunt by the deputation from our Parliamentary Bills Committee, which had considered the whole matter; but there are several others as essential to making up a career adequate to the present day in the position of medical officers while serving afloat or ashore, the principles of which have been admitted as just, but have not been carried into action, or have faltered in their fulfilment, as shown by us last week. The Admiralty will find that the time has come to act *bonâ fide* towards our profession, if it have determined to eradicate discontent from its members in the Royal Navy, and to render its inducements in any degree equivalent to those of the Indian service and the Queen's Army.

The spectacle before them in the results of Mr. Childers's notable scheme, "drawn up", as his late colleague Sir Spencer Robinson informs a contemporary, "by a clever Admiralty clerk", should convince Mr. Ward Hunt of the fallacy of cutting short the service-careers of officers in the executive branch by pecuniary premiums alone, for nothing can compensate to active minds for a too early privation of employment in a service to which they have heartily devoted themselves. These deplorable results will, we need not doubt, guard that able administrator of the Navy from any curtailment of the compulsory age for retirement of those whose services have raised them to the inspectorial grades. His safest policy will, we opine, be found in enhancing the value of those prizes that will allure medical officers onward while activity remains, and in at the same time establishing a fair and just similarity to what obtains in the Army, as portrayed in the eighteenth, nineteenth, twentieth, and twenty-first of the suggestions alluded to; together with the recruitment of seamen, marines, and boys; for who can be so competent as they to select the best *personnel* for manning ships? In these employments combined, there will be found an ample field for providing a trustworthy naval medical reserve, in time of war, of surgeons accustomed to life in ships, even after all have been eliminated who desire to quit the Navy as a life-career after twenty years of active employment in it.

We write with confidence, satisfied that no half-measures will suffice to fill up the great and increasing falling off in the numbers of candidates for this once popular service, to which the mind of the country reverts as to its most natural and most essential defence in the next great war. Let those principles and modes of dealing be adhered to *bonâ fide*, and there need be no fear, we believe, of the future content in the medical staff; but, without them, we feel no confidence whatever in what will be found to be only palliative measures.

DR. HANDSEL GRIFFITHS has been elected a Corresponding Member of the Therapeutical Society of Paris.

DR. EDWARD YOUNG, being about to leave Salisbury, has resigned the coronership of the city and borough; and Mr. George Smith has been elected his successor.

MR. JOHN MILES MOSS has offered £1,000 to the Mayor of Liverpool as the foundation of a fund for improving the streets in the worst parts of the town.

THE City Sanitary Committee have agreed to offer the parish of Clerkenwell the City mortuary for six months, on the payment of 5s. per body.

THE annual dinner in aid of the funds of the French Hospital in Leicester Square, will take place to-day (Saturday), under the presidency of the French Ambassador, His Excellency the Comte de Jarnac. The Lord Mayor and Sheriffs have accepted the invitation to be present.

WE learn with pleasure that Dr. T. Lauder Brunton, F.R.S., was on Wednesday elected Assistant-Physician to St. Bartholomew's Hospital.

At a public meeting held at Denbigh on Saturday last, it was decided to erect a fever infirmary; and a subscription was commenced, which was headed by the mayor, Mr. J. Parry Jones, with £100.

THERE is, we hope, some reason to expect that that most ridiculous institution which calls itself the "Hospital for Diseases of the Heart" will cease to be carried on. Apart from the purposes of "the founder", few of these hospitals have any public or professional *raison d'être*. This most needless institution has long been a caricature of charity; and, as recent circumstances have probably sufficiently disgusted the supporters of it, they will possibly take advice from men of high professional standing, on whose judgment they can rely, and wipe off the overburdened list of institutions this most needless and deformed excrescence of unthinking and misdirected charity.

THE BRITISH MEDICAL BENEVOLENT FUND.

THE annual meeting was held as usual on the 14th instant, Sir George Burrows, Bart., M.D., President, in the chair. The report was read by the Treasurer, Dr. Broadbent, and adopted by the Committee, with an additional clause expressive of their grateful appreciation of his kindness in accepting the office in succession to Dr. Hare, who had held it for seven years. The receipts from donations and subscriptions during the year 1874 amounted to £1620, and the number of grants of immediate relief to cases of distress was 115, including, directly and indirectly, about 250 individuals. The number of annuitants has been raised to 42, receiving from £10 to £20 *per annum* each. A movement has been commenced with the view of raising these, if possible, to an average of ten shillings weekly. Votes of thanks were passed to the retiring Treasurer; to the staff of the Fund; the Auditors (Mr. Hyde Hills and Mr. Parker Young); and the medical journals; also to the Messrs. Churchill, for the use of the committee-room so liberally given; and last, but not least, to the Chairman, Sir G. Burrows, who, in acknowledging the compliment, took occasion, in brief and eloquent terms, to express the pleasure it gave him to be associated with an institution which, in addition to its other claims on the support of the profession, possessed the distinguishing characteristic of affording prompt aid to the distressed and deserving, and, in this way especially, had done so large an amount of good in cases of real misfortune in, as it were, the very hour of need.

MEDICAL MICROSCOPICAL SOCIETY.

At the annual general meeting, held on January 15th, the following officers were elected for the ensuing year. *President*: Dr. J. F. Payne. *Vice-Presidents*: Mr. Jabez Hogg; Mr. H. Power; Dr. U. Pritchard; Mr. Kesteven. *Treasurer*: Mr. T. C. White. *Honorary Secretaries*: Mr. C. H. Golding Bird; Mr. J. W. Groves. *Committee*: Mr. J. A. Ormerod; Dr. M. Bruce; Mr. E. C. Baber; Mr. F. Durham; Mr. H. S. Atkinson; Mr. J. Needham; Mr. G. Giles; Dr. S. Coupland; Dr. W. S. Greenfield; Mr. E. A. Schafer; Dr. W. H. Allchin; Dr. Foulerton.

ATCHISON SCHOLARSHIPS IN UNIVERSITY COLLEGE.

In the Court of Probate and Divorce, on January 26th, before Sir J. Hannen, the case of Sandys v. Atchison was decided. Dr. Spinks, Q.C., and Mr. Pritchard appeared for the plaintiff; Mr. Bayford for the defendant. It was an inquiry into the validity of the will and codicil of Mr. Thomas Atchison, a retired surgeon-major in the Indian army, who died in May last, having, by the papers in question, left the bulk of his property, amounting to something over £5000, for the purpose of founding certain scholarships, to be called the "Atchison Scholarships", in connection with University College, London. The case was heard last week, when the Court pronounced for the papers, but took time to consider whether a certain memorandum which

was referred to in them, and which was executed as a testamentary paper, should be included in the probate. His Lordship intimated that he had come to the conclusion that the memorandum should be included in the probate, and decreed accordingly.

ENTERIC FEVER IN SHREWSBURY GRAMMAR SCHOOL.

DR. W. N. THURSFIELD, Medical Officer of Health for Shrewsbury, has presented a report to the governors of the Shrewsbury Grammar School, on an outbreak of enteric fever which took place in that institution last month. He traces the disease to the escape of sewer-gas from ill-ventilated water-closets and drains; the escape being favoured by the circumstance that the water in the river at the time was high and the discharge from the sewer consequently obstructed. He also calls attention to the existence of a privy with a large cess-pit in close proximity to the larder, from which a direct communication had been made by the burrowing of rats, allowing the escape of foul air. The drinking water used in the school has been the Severn water, artificially filtered; and he advises that, instead of this, which is subject to previous excremental pollution, the water of the town conduit should be used for drinking purposes. He points out that, in such an atmosphere as was found, the standard of vitality in the boys must have been lowered; and that, in fact, it has within the last few years been necessary several times to disperse the school on account of the outbreak of infectious disease. He recommends that a detached building should be provided for the isolation of infectious cases, such as the school possessed two hundred years ago, but which has within the last few years been sold.

THE DEFINITION OF ADULTERATION.

THE Society of Public Analysts at a recent meeting adopted the following as their definition of an adulterated article. An article shall be deemed to be adulterated: A. In the case of food or drink: 1. If it contain any ingredient which may render such article injurious to the health of a consumer. 2. If it contain any substance that sensibly increases its weight, bulk, or strength, or gives it a fictitious value, unless the amount of such substance present be due to circumstances necessarily appertaining to its collection or manufacture, or be necessary for its preservation, or unless the presence thereof be acknowledged at the time of sale. 3. If any important constituent have been wholly or in part abstracted or omitted, unless acknowledgment of such abstraction or omission be made at the time of sale. 4. If it be an imitation of, or be sold under the name of, another article. B. In the case of drugs: 1. If, when retailed for medicinal purposes under a name recognised in the *British Pharmacopœia*, any drug be not equal in strength and purity to the standard laid down in that work. 2. If, when sold under a name not recognised in the *British Pharmacopœia*, it differ materially from the standard laid down in approved works on materia medica, or from the standard under which it is sold. It was also resolved that the following should be deemed limits for the articles referred to under A. *Milk* shall contain not less than 9.0 per cent., by weight, of milk-solids not fat, and not less than 2.5 per cent. butter-fat. *Skimmed Milk* shall contain not less than 9.0 per cent. milk-solids not fat. *Butter* shall contain not less than 80.0 per cent. of butter-fat. *Tea* shall not contain more than 8.0 per cent. of mineral matter, calculated on the tea dried at 100 deg. Cent., of which at least 3.0 per cent. shall be soluble in water, and the tea sold shall yield at least 30.0 per cent. of extract. *Cocoa* shall contain at least 20 per cent. of cocoa-butter. *Vinegar* shall contain not less than 3.0 per cent. of acetic acid.

THE REDDITCH MEDICAL AID ASSOCIATION.

WE have received a handbill purporting to be issued by the "Medical Aid Association for Redditch and District", the object of which is to induce persons to become members. It holds out the strange inducement, that "all parties who enrol themselves previous to December 31st, 1874, will be exempt from medical examination". When a club starts with such a promise, it raises our misgivings, for it looks as if, in its anxiety to obtain members, it were sacrificing one of the chief

securities of a safe and well regulated society. To receive persons suffering from present illness without an extra charge cannot fail to prove a dead weight on the Association. But, on looking more closely at the handbill, there are other features which we like still less. No names whatever are given either of president, treasurer, or committee, to vouch for the character of the Association; nor are the names of the medical officers mentioned. The public of Redditch are, however, assured by Mr. Aston, the secretary, that "the Medical Aid Association offers you a doctor of your own, who will consider it his duty to attend well upon all members, and to give, when necessary, the best and most expensive medicines, including cod-liver oil, quinine, leeches, etc." All these advantages are to be obtained on the following terms: "Male and female members, married, 4s. yearly; male members under eighteen years of age, 2s. yearly; female members under twenty-one years of age, 2s. yearly." The handbill further states: "We take it for granted you are aware of the objections to the system of medical aid which is now in use, and also of the necessity of introducing a better system. After a careful inquiry, we have satisfied ourselves that the association would be a great blessing to its members, and much of the inconvenience felt under the present system would be remedied." That there are drawbacks to the present system of medical aid we have often pointed out; but we should have liked to see a detailed explanation of the "better system" upon which the Redditch Association is to be founded. If the benefit clubs of the town do not adequately supply the medical wants of its working classes, such a scheme as the one before us does not appear likely to remedy the defect. If it be an effort of the artisan population to provide for itself, we fully appreciate the motive; but we fear that the scale of charges is so low, that first-rate medical attendance will not be secured, to say nothing of "the best and most expensive medicines". We should indeed be sorry to hear of any well qualified medical man entering upon a field which seems already fully occupied, by accepting an appointment which, while standing upon an unsatisfactory financial basis, would at the same time make him dependent upon an association which, as far as can be seen, has no high-class or responsible managers.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

THE quarterly court of the directors of the Society was held on January 13th; the President, Sir George Burrows, Bart., in the chair. The acting Treasurer stated that the grants to be made amounted to £1236:10, to be distributed among fifty-eight widows and seventeen children; and three children were to be relieved from the Copeland Fund. The expenses of the quarter were £55:12:5. Three new members were proposed and elected. The Christmas donation to the widows and orphans, voted at the last court, had been given a few days before Christmas to fifty-six widows and twenty children: £5 to each widow, £2 to each child, and £3 to each of the three children on the Copeland Fund, amounting in all to £320. The deaths of two widows receiving grants were announced, and two fresh applications from widows were admitted. It was resolved that a Committee, consisting of the President, Treasurer, and Secretary, should be formed, to draw up a circular stating the advantages to be derived from joining the Society, to be sent to all members of the profession residing within the limits of the London district post and the county of Middlesex. As no anniversary festival will be held this year, the benevolent friends of the charity are invited to send their donations to the Treasurer or Secretary.

THE ABUSE OF HOSPITALS.

SINCE we last referred to this subject, three weeks ago, the following additional names have been added to the list of signatures to the memorial to the Committee of Council of the British Medical Association: Dr. J. G. Davey (Bristol), Dr. Pearson Irvine, Mr. George Lawson, Dr. T. Henry Green, Dr. Tilbury Fox, Dr. Douglas Powell, Mr. T. M. Evans, Dr. Matthew Baines, Dr. Morris (Nottingham), Mr. H. Behrend, Dr. A. R. Graham (Weybridge), Dr. E. West

Symes (Skipton-in-Craven), Dr. George Weller (Wanstead), Dr. W. Bodkin (Chelmsford), Dr. A. Samelson (Manchester), Dr. Alfred Shewen, Mr. J. Higham Hill, Dr. W. A. Guy, F.R.S., Dr. Andrew Fyfe, Dr. John Baber, Dr. Hugh Mackintosh, Mr. G. H. Pedler, Dr. R. B. Painter, Dr. Charles Carter, Dr. Arthur Edis, Dr. John Easton, Mr. Royes Bell, Dr. Spencer Cobbold, F.R.S., Dr. Hunter Mackenzie (Gateshead), Dr. J. L. Gaussen (Antrim), Mr. Francis B. Lee (Heckmondwike), Mr. R. M. Gover, Mr. W. Lattey (Southam), Dr. Boyd, Mr. Allingham, Mr. T. Holmes, Mr. John Scott, Mr. Colin Henderson, Dr. Alex. Henry, Mr. Charles Moss, Dr. Ferrier, Mr. E. J. Nix, Dr. Nankivell (Torquay), Dr. James Hardie (Manchester), Mr. Samuel Wood (Shrewsbury), Dr. Edward Burd, Dr. R. W. O. Withers, Dr. Bindley Talbot, Dr. Alfred Eddowes, Dr. F. V. Davison, Mr. A. G. Brookes, Dr. W. N. Thursfield, Mr. Reginald Hartley, Mr. W. Eddowes, Senr., Mr. W. Grant Farley. The memorial itself we printed at length in our impression of the 2nd instant; and we then mentioned that Dr. Meadows and Mr. Fairlie Clarke would be happy to receive the names of gentlemen who approved of it, and wished to append their signatures.

ST. GEORGE'S HOSPITAL.

MR. PRESCOTT HEWETT, after twenty-seven years' service as Assistant-Surgeon and Surgeon to St. George's Hospital, has resigned. He will be appointed Consulting-Surgeon. Mr. Rouse will succeed him as Surgeon. Mr. Warrington Haward will be one of the candidates for the post of Assistant-Surgeon in the place of Mr. Rouse.—We are requested by Dr. R. J. Lee, with reference to an announcement of last week, to state, that he does not intend to continue as Assistant-Obstetric Physician at St. George's Hospital, and that he is only doing duty till Dr. Barnes can relieve him, when it is his intention to retire from the hospital, and to relinquish the special department of obstetric practice.

THE LATE MR. KIERNAN.

AT the last meeting of the Council of the Royal College of Surgeons, when the death of Mr. Kiernan was officially announced, it was resolved unanimously—"That the President be requested to communicate to the family of the late Mr. Francis Kiernan, F.R.S., the sincere regret with which the Council have received the intelligence of his decease, and to express the warm regard they entertained for him personally, and their appreciation of the eminent service rendered to science by Mr. Kiernan as an anatomist and physiologist." Mr. Kiernan was a member of the Council, and of the Court of Examiners of the College.

THE LATE DR. CHARLTON.

AT a public meeting of the friends of the late Dr. Charlton, held in the Wood Memorial Hall, Newcastle, on December 23rd, 1874—the Mayor of Newcastle, Addison Potter, Esq., in the chair—the following resolutions were passed. "1. That, with a view of perpetuating the remembrance of the late Edward Charlton, M.D., D.C.L., it is desirable to found a scholarship in Medicine at the University of Durham College of Medicine, Newcastle-upon-Tyne, of which body he was President and Joint Lecturer in Medicine; and also to place a bust in marble, or a portrait in oil, in the library of the Infirmary, of which institution he was Senior Physician and Chairman of the Medical Board. 2. That a subscription be forthwith commenced for the purpose of procuring the funds necessary for such an undertaking. 3. That Ralph Brown, Esq., of Messrs. Lamblton and Co., be appointed Treasurer to the fund; that Edward Leadbitter, Esq., and Byrom Bramwell, Esq., M.B., be appointed Secretaries." A Committee, with power to add to their number, was also appointed to carry out the project. The list of subscriptions already promised includes: George Y. Heath, M.D., £105; Sir W. G. Armstrong, C.B., £50; C. J. Gibb, M.D., £52:10; the Mayor of Newcastle (Addison Potter, Esq.), £25; R. Carr Ellison, Esq., £25; John Williamson, Esq., £25; R. Lightfoot, L.R.C.S., £21; G. H. Philipson, M.D., £10:10; L. Armstrong, M.D., £5:5;

C. Arnison, M.D., £5:5; B. Bramwell, M.B., £5:5; C. Gibson, M.D., £5:5; R. C. Clapham, Esq., £5; D. Embleton, M.D., £5; the Gateshead Medical Society, £5; G. H. Philipson, Esq., £3:3; John Philipson, Esq., £2:2; H. O. Ward, M.D., Blyth, £2:2; J. W. Blandford, M.R.C.S., Coxhoe, £1:1.

DR. RUMSEY, F.R.S.

WE hear with great pleasure that Dr. Rumsey is steadily progressing towards convalescence. Happily, his late illness has not in any way involved any depreciation of his great mental power, but is confined to loss of physical power in the right hand and foot. It is, we learn, very widely felt, as we had every reason to anticipate it would be, that Dr. Rumsey's great services to the public and to the cause of public health, which have been highly valuable to the profession, as to the nation, call, under present circumstances, for effective recognition: and it is probable that suitable measures will be taken, in which the most influential members of the profession may be expected to take part.

NEW LUNATIC ASYLUM FOR MIDDLESEX.

At the last meeting of the Middlesex magistrates, a report was brought up from the Committee as to the erection of the third county lunatic asylum at Banstead, stating that the works were being pushed on to completion. The supply of water in the dry season had been tested, and was found to yield 168,000 gallons every twenty-four hours. The report was adopted.

THE SOHO HOSPITAL FOR WOMEN.

WE very much regret to see that two gentlemen have been found to fill two of the long vacant posts at the Soho Hospital. These vacancies were made by the resignation almost *en masse* of the staff. The principal alterations which were needed in the economy of the hospital, and the want of which led to this resignation, have since been effected; but no reparation has been made to the medical staff. The gentlemen who have now come forward are Mr. Reeves (London Hospital) and Dr. Aeneas Munro. The former gentleman is well known in London as an industrious, able, and rising young surgeon. Dr. Munro is a newcomer, we fancy, in London. It required a great deal of a not very desirable sort of courage to take these appointments. Mr. Reeves's resolution will, we imagine, very much surprise and very much grieve his professional friends. A want of professional *esprit de corps* is a very grave defect; and we cannot help thinking that the step which Mr. Reeves has taken is one which is singularly ill-advised, and will create a painful sensation. Any advantages which such an appointment may offer must, we imagine, be more than counterbalanced by its obvious disadvantages. Dr. Munro, in assuming the medical appointment, has chosen to begin his professional career in London under seriously unfavourable conditions. He must not complain if it prove in some respects disappointing. Loyalty to the profession should, we think, be a guiding star for young aspirants to hospital positions; and here we consider that sentiment should have counselled abstinence from office until the *amende honorable* had been made to the late staff. We had expressed this opinion in advance, and see no reason to change it.

SCOTLAND.

ENORMOUSLY HIGH DEATH-RATE IN GLASGOW.

DURING the week ending Saturday the 2nd instant, the death-rate in Glasgow was the highest on record. For the last two days of the week the returns were not obtained in 9 out of the 14 districts, and yet without these the mortality was already 59, and when these are added it will no doubt reach 64 or 65 per thousand. We take the following from the *Glasgow Herald*.

"Taking the death-rate reported for last week, we find that it shows, in the case of pulmonary ailments, an increase of upwards of 100 per cent. over the ordinary average. Obviously this increase is traceable directly to the severity of the weather. As regards general diseases, the increase of deaths is no less than 150 per cent. This state of mat-

ters is very alarming; and as the humbler classes, with few home comforts and fewer friends, are chiefly the sufferers, the prevailing misery cannot at this season be too strongly impressed upon those who are surrounded by all that makes life enjoyable. It is easy to prove, if any proof were needed, that death is knocking loudest at the doors of the poor. In the western districts of the city, where people are well housed, well clothed, and well fed, and sanitary laws are as far as possible observed, the ordinary death-rate is only on an average about 19 per 1,000, being very little above the mean rate of the Registrar-General. The severe weather has brought it up to something like 24 per 1,000, or an increase of 26 per 1,000, this extra mortality taking place principally amongst aged and very young persons. In the poorer districts, again, comprising Calton, Cowcaddens, Anderston, Gorbals, and the Central, the ordinary average death-rate is 34 per 1,000, whereas during last week, still excluding for two days the nine registration districts, the mortality is 68 per 1,000, exactly double the ordinary rate, and representing the extinction of the entire population in 15 years."

Those who lived in Glasgow during the last three weeks of 1874, will hardly be surprised at the enormous death-rate. There was a fog, of no ordinary character. A fog is bad enough, but this was one which could not only be seen, but tasted and smelt. The moisture was evidently impregnated with soot and chemical fumes in the highest degree. Dr. Gairdner, writing to one of the local papers, endeavours to draw a lesson from the fearful rate of mortality experienced. In this letter, he says:

"When dealing with this subject in 1869, under the pressure of what was then considered an extremely high death-rate—though very far short of that which has been lately announced to us—I came to the conclusion, after an elaborate investigation, that manufacturing vapours had probably some considerable influence in increasing the local death-rate from pulmonary causes during northerly and easterly winds; and in particular I pointed out that the purely climatic influences to which the Scottish Registrar-General had attributed the excess of mortality in 1869, had been almost inappreciable in their results in Aberdeen and Perth, and but slight in Edinburgh, as compared with Glasgow and Greenock, although the first three cities are notoriously much more exposed to the merely chilling effects of those winds than the two last. I further remarked that 'among the constant sources of high mortality in Glasgow, diseases of the lungs are always prominent....and that both in Edinburgh and Aberdeen we have examples of cities far more exposed to the influence of northerly and easterly winds in their pure state than Glasgow, and in which, nevertheless, the pulmonary death-rate is not only lower at present, but is persistently lower, than with us.' These conclusions were expressed with all the care and scrupulous reserve imposed by the responsibilities of an official position: but is it not rather a striking commentary upon them that now, in the midst of choking fogs such as every Glasgow citizen has personally experienced of late, we find the death-rate running up to over sixty in the thousand, far in advance of previous seasons in Glasgow itself, and far in advance, also, of every other city in the empire."

And, further on, he sums up in these words:

"Now, if it be a fact that Glasgow and Greenock have habitually, or, indeed, all but constantly, the highest pulmonary death-rate in Scotland, is it not extremely probable that the vapours which, when condensed into a fog, bring about such death-rates as we have had lately, have something also to do with the constant excess of mortality from pulmonary causes in these cities?"

We feel sure that there will be few to differ from Dr. Gairdner in this view, and we hope that something will be done to check the pollution of the atmosphere of the town in the future. It is well known that when the wind blows from the east, it is almost impossible to keep the handles of doors, door-bells, or any polished metal, from becoming rapidly oxidised. And during the late fog it needed only an hour or two to darken the most brilliantly polished door-plate. The air was evidently impregnated with active chemical gases, and these, no doubt, acted on delicate bronchial tubes as well as the more enduring brass.

IRELAND.

SMALL-POX has broken out at Castlebar, co. Mayo, and is spreading throughout several of the districts in that union. Twenty fresh cases have been reported, and five additional are under treatment in the workhouse hospital.

DR. CAMERON'S report for last month shows that 21,000 pounds of unsound meat were condemned as being unfit for food during that period in Dublin.

A TESTIMONIAL is about to be presented to Professor Apjohn on his resigning the Chair of Chemistry in the School of Physic, in Trinity College, Dublin.

IN the Registrar-General's Report for last week, the death of an officer's widow is returned as having occurred at the advanced age of 105.

DR. RAWDON MACNAMARA has been re-appointed the representative of the Royal College of Surgeons for the ensuing year in the General Council of Medical Education and Registration.

HOSPITAL SUNDAY IN BELFAST.

THE last Sunday in December was the day appointed for the collections in the various churches in Belfast for this charitable object. The returns from sixty-three churches which took part in the work, show that £607:16:3 was obtained, an extremely small sum, considering the wealth and population of the town.

ROYAL COLLEGE OF SURGEONS.

WE notified last week that Dr. Cronyn had been appointed as Professor of Midwifery in this institution, in the room of Dr. Sawyer, resigned; but we learn that, since then, he has also resigned, and that the vacancy will be filled up on the 4th proximo. At the late contest for this chair, Drs. Roe, Halahan, A. H. Ringland, J. R. Kirkpatrick, Madden, and Isdell, were among the competitors; and, as it is most probable that the same gentlemen will again compete, we think it likely that Dr. Kirkpatrick will be selected. On the same day, the Fellows will elect a member of Council in the room of the late Dr. Adams. At present, but two candidates have intimated their intention of contesting the post, Messrs. Croly and Corley. The first named gentleman was formerly in the Council, but was obliged to resign from ill health. Little interest is attached to the matter, as the successful candidate will only hold office for a few months, a fresh election taking place in June.

HEALTH OF DUBLIN: QUARTERLY REPORT.

THE returns for the quarter ending the 2nd inst., show that the number of births during that period amounted to 2088, being equal to an annual ratio of 1 in 38, or 27 in every 1000 of the population; and the deaths to 2138, affording an annual ratio of 1 in 37, the death-rate exceeding the birth-rate by 50. The deaths from zymotic diseases numbered 501; scarlet fever causing 238 deaths; fever, 78; measles, 21; croup, 31; diarrhoea, 45; convulsions, 135; bronchitis, 338; pneumonia, 60; heart disease, 05; paralysis, 41; whilst 205 deaths were attributed to phthisis. The average temperature for the quarter was 43.2 degs., and the rainfall measures 9.065 inches.

DUBLIN HOSPITAL SUNDAY.

THE Executive Council of the Dublin Hospital Sunday Fund, held a meeting on the 14th instant, to receive the report of the Committee of Distribution, and to make arrangements for the annual meeting of the friends and supporters of the fund. The total sum realised was £3317:10:3, including interest allowed by the bankers; the expenses amounted to £148:11:9, or 4.4 per cent. on the sum realised, leaving a balance, after distribution of £3000, of £168:18:6. The Committee of Distribution reported that it had distributed the sum of £3000 upon the following principles, contained in instructions given by the public meeting at which the movement was inaugurated, and further instructions given by the Council. The system of distribution was based on the amount of the subscriptions received by each hospital, and the work done during the previous year. In estimating

the work done, the following cases only were taken into account: intern patients, extern midwifery cases, and extern accidents; and the Committee were requested to take evidence as to the approximate relative cost to the hospitals of these cases. With a view of carrying out these instructions, the Committee distributed the fund according to the following plan: 1. That two-thirds of the £3000 to be distributed be divided according to the amount of voluntary contributions received by each hospital during the preceding year: 2. That the remaining third be divided according to the work done (by each hospital) for the voluntary subscriptions received during the preceding year: 3. That 500 extern maternity cases be considered equivalent to one bed maintained throughout the year: 4. That 1000 extern accidents be considered equivalent to one bed maintained for one year: 5. That an allowance of 20 per cent. additional shall be allowed on account of lying-in cases. Applications from ten institutions were received and considered. Three institutions were refused on the following grounds. "The Provident Infirmary is an institution professedly admitting none but paying patients. The Cripples' Home not yet having been established, the application from that institution could not be entertained. The Dublin Infirmary for Diseases of the Eye and Ear (Ely Place), appearing to be conducted without a committee or trustees, such as is usually the case in public hospitals, was, in the opinion of the Committee, more of a private than a public institution, and therefore not entitled to a share in the funds at its disposal." The awards made by the Committee were as follows: Sir Patrick Dun's, £335:17:5; City of Dublin, £1160:17:2; Steevens', £312:0:4; Cork Street, £121:3:3; Mercer's, £387:18:10; Rotunda, £407:1:10; Coombe, £215:2:7; St. Mark's (Ophthalmic), £59:18:7; total, £3000. The Committee made the following remarks with regard to two of the institutions which opposed the movement. In reporting to the Council the result of the first year's distribution of the Hospital Sunday Fund, the Committee think it right to remark that, in consequence of the refusal of some of the institutions to participate in the funds, the sums awarded to the various participating hospitals have necessarily been proportionately larger than they would have been had the others been willing to unite. Of these, there can be no doubt, the Meath and Adelaide Hospitals were entitled to claim a share of the general fund, had the authorities of these institutions considered it to be to their interests to do so. With a view to show how the fund would have been divided had these two hospitals been included, the Committee has thought it right to estimate, as nearly as possible, the amounts to which they would have been entitled if participating, and the consequent result to the other institutions now obtaining share of the fund. The amount calculated, from the information furnished by the published reports of these institutions, would appear to be about as follows: Not participating in 1874—Meath, £435:7:11; Adelaide, £668:3:4; Participating in 1874—Sir Patrick Dun's, £200; City of Dublin, £739:1:6; Steevens', £195:4; Cork Street, £75:19; Mercer's, £255:18; Rotunda, £225:11:6; Coombe, £135:18:9; St. Mark's, £48:16; Total, £3000. The Distribution Committee also recommend the adoption of a definition of an hospital, such as will include all institutions, either of a semi-private character, or of the nature of asylums for the incurable. The inauguration of Hospital Sunday in Dublin has been clearly a success, in spite of all the opposition with which its promoters had to contend.

REPRESENTATION OF DUBLIN UNIVERSITY.

THE contest was brought to a termination on Friday, the 22nd inst., and resulted in an easy victory for Mr. Gibson, who secured nearly as many votes as both his opponents together, the numbers being, Mr. Gibson, 1210; Mr. Miller, 759; Dr. Traill, 538. Dr. Traill did not canvass, nor, to the best of our belief, did he issue any address, so that rumours were prevalent that he had withdrawn from the contest. We hope that on the next occasion Dr. Traill may be successful, as we believe that medical representatives are much wanted in Parliament.

THE SANITARY CONFERENCE AT BIRMINGHAM.

[Continued from page 120 of last number.]

Dr. Goldie on the Condition of Leeds.—*Dr. Trench on Overcrowding in Liverpool.*—*Mr. J. Leigh on Removal of Accumulated Matters liable to Putrefaction.*—*Dr. Foster on the Comparative Mortality of Birmingham.*—*Discussion.*

THE CONDITION OF LEEDS was the subject of a paper by Dr. GEORGE GOLDIE, in which he dealt with the population, trades and sanitary statistics, and river-pollution of the town. The water supply of the town was formerly taken from the river Aire; this, however, had become so polluted that it was necessary to change the source of supply, and an ample and good supply was now obtained from the river Wharfe, and the future source would be still better, for the Wharfe was not free from organic impurities. A close supervision was especially kept on all cottage property that there should be an ample supply of water; and, under such close supervision, thirty-nine impure wells had been detected and closed. In many cases, these wells contained all the impurities of the sewers. The ventilation of the sewers was carried on in as many points as possible through the gullies in the open streets. The dipstone by the side of the gullies had been perforated, and thereby allowed, at one time an upward, and at another a downward, current. Dr. Goldie was informed that this plan was held in high estimation by the sanitary authorities, but he would be glad to hear the opinions of his colleagues on the matter. In large manufactories, boiler-flues might be made to serve as ventilators, by consuming the dangerous gases. The structural character of the town was very deficient, and health and morality had both suffered in consequence; but under the power vested in the corporation, by the Artisans' Dwellings Act, he was led to hope for better things. The authorities had not been idle. Courts and yards had been opened up, and 674 houses condemned as unfit for human habitation, and demolished. Dr. Goldie thought that the Public Health Act, 1866, sec. 19, subsec. 1, gives powers to deal with overcrowding as a nuisance, and he intended to test its powers. The Adulteration Act had been put in force with great benefit to the inhabitants. The system of public slaughter-houses was severely condemned, and the establishment of public abattoirs recommended.

Dr. TRENCH, the Medical Officer of Health for Liverpool, had prepared a valuable paper on the Overcrowding which there prevails. It was read in his absence by Mr. Deacon, borough engineer of the town. Overcrowding had its origin in Liverpool and other Lancashire towns as early as the latter half of the eighteenth century. The population of Liverpool had increased sixfold between the years 1801 and 1871, i.e. from about 81,600 to 493,346; and the housing of this rapidly increasing population was neither regulated by building laws nor cared for by municipal responsibility, but was left to the private and uncontrolled enterprise of small capitalists, whose sole object was gain, and who were without care for the health of the people or the welfare of the future community. Of the many evils springing from this state of things, the erection of courts and the construction of cellar-dwellings, were the chief physical causes of the sickness and mortality of the town. In 1864, the Town Council obtained legal powers to deal with and improve the courts at the public expense. The principle and machinery of the provisions of the Act were as follow. The medical officer of health reported on premises in or adjoining the courts which, by reason of their condition or situation, required improvement. That report was laid before the Town Council and the Grand Jury of the Borough Quarter Sessions. The town-clerk served every owner of premises affected by the report with notices, stating the nature of the alterations required by the medical officer, and the time when the grand jury would inquire into the matter. The grand jury, by deputation, inspected the premises, received evidence, and then reported. A presentment was framed by the grand jury on the report. The borough engineer then prepared plans and specifications of the works required to carry out the presentment. Notices were again served on the owners of premises, telling them when and where they might inspect these plans and specifications. If any owner objected to the works, he might go before the justices and discuss the propriety thereof, and the justices might make such order as they thought fit. The corporation and the owner of the premises might come to some mutual agreement as to the amount of compensation to be paid for the alteration or demolition of the premises; and if their valuation were not accepted, then the decision was left to a jury under the Lands Clauses Act. On tender of amount of compensation, the corporation might execute the work. Under this Act, five presentments had been made by the grand jury, requiring the demolition of 542, and the alteration or partial demolition of 115 houses, and the erection of trough water-closets in lieu of privies for the courts. The whole of this had been effected at a

cost of £87,663, including parliamentary and legal expenses. The Council had also required that all the privies in courts not affected by presentment should be removed and converted into trough water-closets at the cost of the owners. Dr. Trench illustrated the effects of the structural alterations in improvement, by comparing the fever-maps of 1865 and 1868. With regard to objections which might be made against the policy and principle of the Local Act, it might be said that it was contrary to justice and to the doctrines of true political economy to improve private property at the public expense; and that no portion of the ratepayers' money should be expended without the direct control of their representatives. The structural alterations, required, however, were in the form rather of the provisions of a town's improvement than of a nuisance removal act. The houses or premises ordered to be demolished, were not themselves necessarily injurious to health. They might be well built, airy, and habitable, and with a street frontage; yet their demolition was required because, by reason of position or situation, they blocked up the entrance of courts, and impeded the circulation of air to blocks of buildings. The Artisans' and Labourers' Dwellings Act enabled the local authority to have the obnoxious premises altered or demolished instead of closed. In Liverpool, the closing of houses unfit for human habitation led to their speedy improvement. The real impediment, however, to the beneficial working of the Liverpool Act would be found in the imperfect provisions of the Local Government Act, 1858. The thirty-fourth section of that Act empowered local boards to make bye-laws with respect to the sufficiency of space around buildings; but it had been held that such bye-laws could not apply to additions to, or extensions of, buildings erected before the passing of the Act, or before its adoption by a local board or a council of a borough. It was thus that, even in new districts of the town, buildings, having no separate area belonging to them, might be so placed as to injure the healthiness of blocks of houses, while, in old districts, owners were permitted to place stables, shippens, sheds, and workshops on every open space in existing yards. What was wanted, before local authorities attempted to improve the sanitary condition of the houses of the labouring class, was the compulsory passing of bye-laws for space around all newly erected buildings, without reference to whether such buildings were to be used for habitations or not. Of course a discretion must be left to the local authority to relax in special instances, if necessary, the stringency of these bye-laws, so as not to interfere with trade, or not to prevent the transition of a residential to a trading or manufacturing district. In all cases the medical officer of health, and the engineer, should be required to report on the effect on health of all relaxations of bye-laws before being sanctioned by the Council.

Mr. J. LEIGH, Medical Officer of Health for Manchester, read a paper on the Removal of Accumulated Matters liable to Putrefaction. This subject early engaged the attention of the Health Committee. The committee had been led to the adoption of the dry system, and the objects aimed at were:—Frequent removal of the excreta, so that time should not be allowed for putrefactive fermentation to take place; small closets to necessitate frequent removal; the partial deodorisation of the excreta; exclusion from the receptacles of all such matters as should diminish, to a serious extent, the manurial value of the excreta; the conveyance of any emanations from the closets to such an altitude by flues as should bring them into the general currents of the atmosphere; the exclusion of all excreta, solid and liquid, from the sewers; the collection of all household rubbish in a receptacle separate from that used for collection. The system in use in Rochdale was adopted. About 13,000 of these closets had been constructed in Manchester, replacing, to this extent, a number of reeking cesspools. The larger number were emptied twice a week, clean and dry ones being put in their places, and some were removed almost daily, and a few at intervals of once a week. On removal, they were covered with tightly fitting lids, and were conveyed away in closely covered vans. The almost entire absence of odour from these closets was remarkable. The readiness with which disinfectants could be supplied was also an advantage, whilst the ease and frequency of removal, in a time of epidemics, were great recommendations. The infectious dejections were not allowed to remain long, and the poisons were not carried to other houses or closets. The drains of the courts and passages of the city were ventilated. An examination of a large number of the drains and sewers, three years ago, showed that the interior of them was nearly blocked up with a black and fetid composition of fine ashes, coal and cinders, and excreta. As the altered privies were entirely disconnected with the drains, such an accumulation could not now take place. Manchester, however, was emphatically a privy or midden town; for, although there was a moderate number of water-closets, yet these constituted but about a sixth. The sewage of the densely populated districts would probably be so diluted by the enormous volume of water with which it would be

intermixed under the condition of things which they would bring about, that the simplest filtration or precipitation, should either be required, would be sufficient to purify it for its passage into rivers. The nuisance-inspectors (nineteen in number) had to report immediately the existence of any infectious disease. The rivers Irk, Mersey, and Irwell received the sewage of the city, and were in a very black and somewhat odorous condition. By the reconstruction of closets, the fouling of the rivers might not be of a very injurious character in a few years. Manchester had a good supply of pure water, and the streets were well paved and sewered.

Dr. BALTHAZAR FOSTER, Physician to the General Hospital, Birmingham, read a paper on the Comparative Mortality of Birmingham. In a tabular form, he gave the rate of mortality from all causes, and certain special causes, for twenty-years (1851 to 1870), in Birmingham, and six other large towns, as compared with the rate of mortality in the country generally (England and Wales) and in twelve healthy rural districts. It appeared that the death-rate of the Birmingham district, from all causes, placed that town higher in the health scale than Liverpool, Manchester, Leeds, and Sheffield, while the death-rate was greater than that of London, and exceeded that of the whole country by about 4 per 1,000. The reduction of this excess was the work before the sanitary authorities of these districts. The two great blots in the sanitary records of Birmingham were the diarrhoea and diphtheria death-rate. The diarrhoea death-rate was twice as bad as the average of the whole country, much worse than that of London and Bristol, about equal to that of Sheffield and Leeds, and was only exceeded by the death-rate in Manchester and Liverpool. It had to be remarked, however that, during these twenty years, Liverpool had suffered from several cholera epidemics, while Birmingham had enjoyed a wonderful immunity from this. The town had improved during the last ten years, but not sufficiently to justify any complacent inference to the deplorably high death-rate from diarrhoea. As to diphtheria, Birmingham was the worst great town in England, and this unenviable character had been acquired during the last ten years. The death-rate from this disease had gone up from .07 to .34 per 1000; 750 deaths had occurred from diphtheria during the latter decade, against 147 in the former. As to zymotic diseases, Birmingham was but little better off in this last decade than in that ending 1860. Dr. Foster specially referred to this, for these diseases were what was fairly called preventable. Their propagation depended on neglect of sanitary laws. The simple statement that the death-rate in Birmingham from preventable disease had been for twenty years past about 7 per 1000, or that more than one-fourth of the total deaths had been from this cause, hardly conveyed the magnitude of the evil. Every year there were now 2,000 deaths from this class of preventable disease, and during the twenty years considerably over 30,000 persons had died in Birmingham from a class of disorders largely reducible by strict sanitary measures. Diphtheria and diarrhoea came under this category. Both were eminently preventable; from both had the town suffered heavily. The question naturally arose: Were the special conditions in Birmingham favourable to the development of these diseases, and, if so, what were they? In 1870, there were 70,000 houses connected with privies and middens in the town. These houses contained a population of 325,000. In the words of the report of the Sewage Committee: "The middens cover an area of thirteen and a half acres, and practically all of them, containing fecal matter and solid and liquid refuse, are open to the air." The sewers were consequently fouled by drainage from the middens, and the surface-wells became the receptacles of sewage-matter with which the earth was absolutely saturated. The water of these surface-wells was at present used by at least one-third of the population. Some 140,000 people in this town drank this death giving fluid, and especially the children under five years of age, on whom the mortality from diarrhoea and diphtheria fell most heavily. The remedy for this state of things were (1) the abolition of the midden system, and the substitution of a system of weekly removal of refuse of all kinds from every house; (2) the abolition of all surface-wells, and the substitution of a constant supply of the purest water that could be got. If, by any means, said Dr. Foster, a constant stream of pure water is poured into our courts and yards, in place of the tainted well-water which is now used, our health conditions in Birmingham will be greatly improved, and our mortality from preventable diseases largely diminished.

The foregoing papers were read during the morning sitting. In the discussion which followed,

The MAYOR of CARLISLE asked Mr. Goldie what arrangements were made for the inhabitants of the houses which had been demolished, and the cellars that had been closed. He generally found that, if the poor were removed from the cellars, they went into garrets.

The MAYOR of PORTSMOUTH was quite sure that it would be interesting if he stated the cause why, in his opinion, the town he

represented had the lowest death-rate of any of the eighteen large towns. It arose from the fact that the four towns, which constituted the municipality, had a large acreage of ground surrounding them; and, also, that the authorities rigidly enforced the bye-law, which required ample ventilation and open spaces be provided for all buildings.

The MAYOR of DUDLEY said that the local authorities had ample powers granted to them to deal with the evils which had been alluded to; but, unfortunately, they did not know how to apply them. If (he said) you wish to deal with the water supply, the isolation of fever cases, drainage, uninhabitable houses, wretched privies and ash-pits; in fact, upon any subject that is reported upon by the medical officers of the local governing bodies, you have power given by some Act or another to deal with it.

Dr. HUMPHRY SANDWICH, C.B., said that he represented no town, city, or community. In London, millions, not accidentally, but systematically, had provided for them more or less diluted sewage-water as their daily drink. This might appear a sensational assertion, but he would appeal to the result of a chemical analysis of the water furnished to the metropolis during the month of December. "In the water of the Grand Junction Company, living and moving organisms were found, and in the Chelsea Water Company's water were contained particles of linen and woollen fabrics, with fibres of partially digested and decomposed meat." Dr. Frankland added that the water thus charged with fecal and other refuse matters was unfit for dietetic purposes, and could not be used without serious injury to the health. He (Dr. Sandwich) saw upon the platform one of our legislators, and he begged to inform him that the water furnished to the eating-room of the House of Commons was thus composed. He ascribed all this to a boasted and comparatively modern invention, the water-closet. In doing away with the cesspools, millions of cesspools were made, all connected together, never properly cleansed, and communicating with the interior of dwelling-houses. Dr. A. Carpenter and other authorities, in maintaining the good of water-closets, told us how easily sewage farms might be arranged; how the water might go through certain processes by the operation of filtration beds, and then how the effluent water might result pure and free. But the organisms, these marvellous seeds of disease, were not discoverable by the microscope or by any chemical agency. Moreover, even admitting, as one of the previous speakers had done, that healthy excrement was not deleterious, all must agree that it was very nasty. The water containing the excrements, in all inland towns, must go into the river. Consequently, it must necessarily poison the source of supply of all towns below. He thought almost anything better—most assuredly the pail system; and, in his opinion, the best system of all was that of Captain Liernur.

Mr. Alderman TATHAM of Leeds spoke on the subject of sewer-ventilation, in which he said that the trap system of ventilation had proved a failure, and, in consequence, they had had their gullies untrapped, on the principle that it was better to have sewer-gas outside rather than inside the houses, and the town had benefitted greatly in consequence.

Mr. CHALLINOR of Leek said the grand thing was to obtain the co-operation of the people. That had been done in Leek; and, during the last twenty years, from having been one of the worst sanitary towns in the kingdom, it had now become one of the best.

Dr. HIME of Sheffield said that one result of the Conference would, no doubt, be the removal of the opprobrium cast on the medical profession. He said that ventilation and cleanliness were only secondary agents at the best, and something else must be done to solve the question of the origin of disease, and diminish the death-rate. In the same part or district the rate of mortality was found to rise from twenty to thirty or thirty-five per 1,000 in a few weeks. Was it to be supposed that, in this town, the people become more cleanly or more uncleanly, or that their manner of life was more moral, or that they had better ventilation? The water-supply was also looked upon in the same aspect. It seemed to him that, before undertaking to knock down houses and turn people out, although, doubtless, in some cases this might be necessary, it would be more wise and useful to strike at the root of the matter, and find the causes of the disease—the primary moving agents favouring the development and growth of zymotic disease. He was opposed to the idea that any amount of dirt would produce a case of typhoid fever, or that the most stringent cleanliness would preserve a neighbourhood from an attack of the disease. Allusion had been made to the merits of water-closets, and to the relative methods of dealing with the sewage question. With reference to that, his advice was—first catch the sewage and then utilise it.

Dr. FERGUS of Glasgow exhibited sections of Lead Pipes which had been decomposed by the action of sewer-gas, and gave, as his experience, that the term of existence of a sewer-pipe was but fourteen years.

Dr. VELD, the Medical Officer of Health for Sunderland, stated the

steps which had been taken to improve the sanitary condition of that town, and strongly urged the use of sea-water for flushing sewers, ventilating streets, and other sanitary purposes, on the ground that it was more suitable for those purposes than fresh water.

A few remarks were made, and the proceedings of the first section were brought to a close.

The afternoon was occupied in considering the question of working men's dwellings, the evils of every kind which arose from insufficient and unsuitable habitations were fully recognised, and various suggestions made for their remedy. Papers were read by Sir Sydney Waterlow, the vice-president of the Shaftesbury estate, and Mr. Martin of Birmingham; and a long discussion followed, in which Sir Charles Reed took part, and earnestly urged the claims of the lower-class poor, who were verging on pauperism, to consideration.

THE HAMPSTEAD HOSPITAL SITE.

IN a letter to the President of the Local Government Board, the chairman of the various committees appointed for the purpose of opposing the erection of the Hampstead Hospital have made one more attempt to make out a grievance. They have urged nothing new or valuable in support of their case; they have not produced a single authenticated case of small-pox communicated from the hospital; they have not brought forward any medical man of special experience in the question under discussion to say that they have any cause for complaint; and, as if to do the best they could to destroy their own cause, they admit, what they have hitherto most strenuously denied, and indeed do in this present letter deny, not only that they may have failed to detect isolated cases of small-pox occurring before the hospital was opened, but that five cases did actually occur seven or eight months previously to its opening. In order that there may be no doubt about this, we will quote their own words. In page 4, they say:—"The Committee can state that a careful inquiry made at the time of the epidemic, and since repeated, has failed to discover that there was a single case of small-pox in Hampstead at the time of the epidemic, until patients suffering from the disease were introduced into the parish by the Metropolitan Asylums Board." But in a foot-note on the same page, they say: "The only cases of small-pox in Hampstead prior to the opening of the hospital which the Committee have been able to discover are four or five cases that the health-officer has brought to their knowledge, and which, he states, occurred in March or April 1870: *i.e.*, seven or eight months before the hospital was open for small-pox patients." How does this statement harmonise with the frequently repeated assertion, that there was not a single case of small-pox in the parish of Hampstead until after the opening of the hospital? Five cases are actually admitted to have occurred by the Hampstead Committees themselves months before the hospital was opened, and we may fairly conclude that this does not exhaust the number. It is just possible that an attempt will be made to escape from the conclusion which necessarily follows from the last mentioned admission, by means of the words, "at the time of the epidemic". It may be contended that small-pox was not really epidemic in London until the latter part of the year, and that there was therefore no connection between the cases which occurred in Hampstead after the opening of the hospital and those which occurred in the early part of the year. This is a line of argument which can neither be proved nor disproved, and as such it is of no value to us in the present discussion. Taken in connection, however, with the mode in which epidemics arise, the fact that there was small-pox in Hampstead and in Kentish Town in the early part of 1870 is of the utmost importance. Epidemics do not commence by an explosion; they arise as isolated cases scattered about here and there, attracting little or no attention; these gradually increase, the rapidity of increase depending upon a variety of considerations, such as susceptibility of population, nature of disease, water-supply, habits of life, and general sanitary conditions. To enter into a discussion as to when any epidemic began would be a fruitless proceeding; but, as regards the small-pox epidemic of 1870-71, this much is clear in reference to the north-west district of London, that, in the month of March or April, there were five known cases of the disease, and that in the week ending July 23rd there was one death, representing from ten to twenty cases, in Kentish Town. In the week ending October 1st, a second small-pox death is registered in the same district, and in the month of November two deaths from small-pox were registered there. We have thus the important facts, that small-pox had been hanging about Hampstead and Kentish Town from an early period of the year 1870, and that in the latter district, in the month of November—the month immediately preceding the opening of the hospital—there were, judging from the two deaths, probably thirty or forty small-pox cases in

the said district—a district which is only distinct from Hampstead in name—before a single case entered the Hampstead Asylum; and notwithstanding, it has been asserted that small-pox in Kentish Town and Hampstead was due to the existence of the Small-pox Hospital.

The most foolish, perhaps, of the representations of the Joint Committee is that which represents Hampstead as a district perfectly distinct and separate from London. They constantly speak of it as if it were a small village or town having little or no communication with the great city, as if it were a place where the existence and extent of disease could be easily known and defined, and where, from the limited nature of the communications between other places and itself, the origin of disease could be readily traced. On the contrary, Hampstead is an integral part of London, joined to it in the closest manner by continuous lines of building and numerous streets, and through these the freest communication takes place daily between it and the more central parts of the metropolis. If it be admitted that Hampstead forms an integral part of London, and that there exist innumerable channels by which infection might be conveyed to it from various quarters of the city: that it is bounded by a district in which small-pox actually existed long before a single small-pox patient entered the Hampstead Asylum; that stray cases existed in the district itself; and, lastly, that the Hampstead Committees have not yet, though often called upon, traced one single case to the hospital,—it may, we think, be fairly said of the proposition which we are contesting, that it is not proven and highly improbable. All this is confirmed by the emphatic statement of Dr. Stevenson, the health-officer for St. Pancras, and by the silence of Mr. Lord, the health-officer for Hampstead. That the existence of the Hampstead Hospital contributed nothing to the spread of small-pox may be inferred from the fact, that districts without such a hospital as Hampstead suffered in greater proportion, as the following figures extracted from the Registrar-General's returns will show.

	Population in 1871	Deaths from week ending July 9, 1870, to week ending Aug. 3, 1870.	Ratio per 1,000
Hampstead...	32,271	1,358 1,332*	...
St. Pancras Division:			
Regent's Park ...	38,192	48	0.8
Tottenham Court Road ...	39,360	48	1.22
Gray's Inn Road ...	29,216	50	1.71
Somers Town ...	38,562	137	3.56
Camden Town ...	18,066	41	2.26
Kentish Town ...	68,198	188	2.75

This requires correction for cases removed to any hospital, but probably the sequence of prevalence in the several subdistricts would not be altered.

The Joint Committees, whom, without disrespect, we may regard as without special knowledge on the subject, call in question the general policy of the Metropolitan Asylum Board in erecting large hospitals for the treatment of infectious diseases, on the ground that certain eminent, but unnamed, members of the medical profession are opposed to such hospitals; and they quote statistics from Dr. Gibbon, who, in a report to the Holborn Board of Works, showed that the mortality from small-pox treated in large hospitals was twice as great as that of patients treated in their own homes. Conclusions drawn from such insufficient data as those produced by Dr. Gibbon must be of little value; and, even if we were to admit the data furnished us as sufficient to justify in making deductions, the only conclusion to be drawn would be that all small-pox patients should be treated at their own homes, a conclusion from which even the Joint Committees would probably recoil. Moreover, in the Highgate Small-pox Hospital, which is a small hospital, the mortality of 2,654 cases, treated during the period from 1836 to 1851 inclusive, was 37 per cent., *i.e.*, just 17 per cent. greater than the Hampstead Hospital mortality, which was only 20 per cent. The treatment of epidemic infectious diseases in small hospitals, if practicable, would be excessively expensive, would necessitate the employment of a larger number of medical officers, nurses, cooks, and servants, all of whom would be liable to contract the disease. New appointments would require to be made as the original holders fell sick, and so on *ad infinitum*. In this way, the hospitals would become, to a not inconsiderable extent, places for the dissemination, not the repression, of disease. If, too, hospitals were too near the dwellings of the patients, it would be more difficult to restrict visiting; and the long walk which many poor people have to take after leaving a hospital situated at some distance from their homes, exposes them to the influence of one of the best and surest of disinfectants, to wit, fresh air. It appears, too, to be forgotten that it is not the bulk of a hospital which renders it unhealthy.

but the overcrowding of it; and this may clearly occur in a hospital constructed for ten patients as in a hospital constructed for a thousand.

In reference to the alternative site which the Joint Committees have offered to the Asylum Board, they quote, and justly, Dr. Murchison as a high medical authority. We commend to their attention the following extract from his work on *Continual Fevers*, on the subject of fever hospitals.

"On the one hand, it is believed that 'it would be better to have no hospitals at all than to mix cases of typhus, small-pox, and scarlet fever with patients suffering from other diseases'; while, on the other, certain non-professional sanitary reformers, endowed with more zeal than knowledge, have proclaimed to the world that all cases of infectious disease ought to be distributed through the wards of general hospitals, and that fever-hospitals and fever-wards are at all times 'a crime against humanity and a disgrace to the age in which we live'.

"The objections which are usually urged against fever-hospitals and fever-wards are two, viz.: first, that the concentration of the poison increases the mortality among the patients themselves; and, secondly, that the concentration of the poison increases the danger to the attendants.

"But these objections, which are too often made, without reflection on what would be the alternative if all cases of fever were admitted into general hospitals, apply only to fever-hospitals which are overcrowded or badly ventilated.

"If 2,000 cubic feet of space be allowed to each patient, and if there be thorough ventilation, there need be no more concentration of the poison in a fever hospital than in a general hospital with a sprinkling of fever cases.

"Take, for example, the London Fever Hospital. It has already been shown that the rate of mortality for each individual fever has not been greater than what has been observed in most general hospitals (see pages 217, 366, and 520), while, during fourteen years (1848-61), 3,680 cases of true typhus fever were treated within its walls; but the disease was only communicated to 53 persons, of whom 14 died. In other words, only one person caught the fever for every 70 under treatment.

"What would have been the consequences if these 3,680 typhus patients had been distributed among the general hospitals of the metropolis, may be imagined from the comparison about to be made.

"During the first six months of 1862, 1,107 cases of true typhus were under treatment in the London Fever Hospital, of which 232 died, or the mortality was 20.95 per cent. In the same period, 343 cases of typhus were under treatment in six of the general hospitals of the metropolis mentioned below, of which number 80 died, or 23.32 per cent.

"The 1,080 (1,107-27) cases admitted into the Fever Hospital communicated the disease to 27 persons, of whom 8 died. In other words, only 1 person took the fever for every 40 admitted, and only 1 died for every 135. But the 272 cases admitted into the six general hospitals communicated the disease to 71 persons, of whom 21 died; or 1 person caught the fever for every 38 cases admitted, and 1 life was lost for every 12.9 cases admitted. What would have been the result if there had been no Fever Hospital, and if the 1,080 cases admitted into it had been distributed among the general hospitals in addition to the few hundreds which were actually treated in them? Yet, in the midst of this epidemic, the abolition of the Fever Hospital has been advocated!"

As specimens of the careless haphazard sort of way in which this report has been got up, we proceed to give some instances.

Having disposed of the question of the evils arising from the existence of large hospitals, the Committee proceed to enumerate the reasons, to prove the ineligibility of the site selected for the erection of the present one; and first among the number comes that of "want of proper isolation". One, of course, expects to find something on the subject of isolation—something to show what proper isolation is and what it is not. Instead of any information on these points, the committee proceed to express their astonishment that the asylum managers should have stated that only two cases of small-pox occurred in the houses in the immediate neighbourhood of the hospital, instead of seven as they assert, a circumstance which throws no light on the question of isolation, unless it were shown that the said cases could be traced to the hospital influence, which the joint committee do not attempt to do. They simply make an assertion.

Again, speaking of the number of cases which occurred in Fleet Road, and Upper Park Terrace, they say, "if the above lamentable results followed when the hospital was employed for patients suffering from small-pox, a disease against which the great majority of people were doubtless protected by vaccination, what may not be expected if it be used for diseases so contagious as typhus or scarlet fever, against which there is no protection?" Now, what the recent small-pox epidemic proved was, that the great majority of people were not protected by vaccination. The majority had been somewhere vaccinated,

but a very few indeed had been efficiently vaccinated. Had they been so vaccinated, they would not have had small-pox. Criticising the asylum managers' statement, that the houses immediately surrounding the existing hospitals are free from fever, they forget that Dr. Aveling states that, in the City of London Union, which contains eight hundred inmates, and is within a few feet of the hospital, *no cases of fever have occurred*; and we feel justified in saying, from personal knowledge, that in the other houses surrounding the hospital, not only have no cases been known to be traced to its proximity, but that none have occurred.

Professor Owen is quoted with evident satisfaction, as if his letter supported their cause. If it did, it would be of scant value, inasmuch as the distinguished professor has no special experience on the subject. But it does not. The substance of Professor Owen's letter is summed up in the following words, viz.: that the responsibility of erecting infectious hospitals is a grave one; that the obligation to make an exhaustive search for an unobjectionable site is imperative, and that events may make the neglect of such search culpable; to all which we cordially agree, and we imagine the asylum managers agree too.

We have not space to devote to Dr. Murchison's report the full consideration which the opinion of one so well qualified to speak merits. We shall limit ourselves to the question of how far the noises from the trains would be injurious to the patients, if the hospital were to be built on the site offered by the Hampstead committees. Dr. Murchison says that with him the objection has little weight, inasmuch as the patients are very "often deaf and rarely suffer from noise; while the noises inside a ward containing delirious patients are far more serious than any noises from without". It is quite true that deafness exists in some cases of fever, but it does not exist in all, nor in any during the whole period of the fever. As regards typhus fever, Dr. Murchison only asserts its existence in one half of his cases (epidemic of 1862). Of enteric fever he says: "Deafness of one or both ears is a common symptom. I noted it in 20 out of 46 cases; Lewis observed it in 58 of 99 cases; Barth in 36, of 129 cases; and Jenner in 6, of 23 fatal cases. It is rarely observed before the end of the second week". Thus out of 297 cases, the symptom occurred in only 120 cases, and, in the majority of these, the patient had passed through two of the three stages into which, in the majority of cases of enteric, the fever may be divided; and by the end of the third week the deafness would in most cases have disappeared, and the patient, with a nervous system rendered more sensitive by disease, would be more than ordinarily liable to feel the effects of noise. Of relapsing fever, Dr. Murchison, says "that deafness is not a common symptom. In 220 cases, Douglas met with it only twelve times; and in eight cases it was very slight, and only lasted a day or two. Of the four cases where it was decided, it occurred early in the attack in one, and, in the remaining three, it only came on in convalescence." On Dr. Murchison's own showing, then, deafness in the majority of cases of continued fever is absent, and even when it occurs, it exists for but a short period. It ought to be remembered, too, that in some cases of fever, extreme intolerance of sound exists, and the loud noises, whistling of engines, shouting of porters, and the shunting of waggons, which would be going on day and night at a main shunt, could scarcely fail to drive such patients frantic. In regard to noises made in wards from delirious patients, it appears to us a defect in hospital management if patients so noisy as to disturb their neighbours be not isolated.

No one knows better than Dr. Murchison the importance of sleep in fever. On this subject he says: "The practitioner cannot be too forcibly impressed with the fact, that loss of sleep, at any stage of typhus, if it continue for two or three nights, is of itself sufficient to kill, and that even the shortest sleep is an advantage to the patient." The effect of trains in preventing people, fresh to their neighbourhood, from sleep, is too well known to require evidence. The effect is greatly exaggerated when to the noise of a simple train is added the much greater noise of a junction where trucks are being shunted day and night. We were informed, on our visit to the site, that people in the neighbourhood, when sick, feel the annoyance which the junction causes; and that persons fresh to the place do not sleep for the first week or two. These reasons are, we think, absolutely fatal to the Mill Lane site.

VOTE OF THANKS.—At a special meeting of Court No. 545 of the Ancient Order of Foresters, Leek, to appoint a medical officer, the following resolution was passed. "That this meeting regrets the resignation of Charles Heaton, Esq., M.D., as their medical officer, and unanimously tender to him their gratitude and thanks for the services he has rendered as an eminent and skilful surgeon, for the judgment he has ever displayed in the interest of the court (the present prosperity of which is the best proof), and also for the considerate kindness he has invariably shown to the members."

EXPERIMENTS ON ANIMALS.

AN influential deputation from the Society for the Prevention of Cruelty to Animals presented, on Monday last, a memorial to the Council, asking that the Society would vigorously pursue the course commenced by the prosecutions at Norwich. Sir William Fergusson and Mr. Tufnell are referred to as "two eminent surgeons who pronounced the experiments of M. Magnan needless and cruel". The memorialists state that vivisection is now "the daily exercise of hundreds of physiologists and young students"; and that the "ambition for scientific notoriety may be deemed a not insignificant motive for the performance of many of these experiments". They recommend that these objects may be carried out—

1. By the appointment of a subcommittee expressly to deal with the subject, to be called the "Subcommittee for the Restriction of Vivisection"; 2. By instructing Mr. Colam to undertake as many prosecutions of cases of vivisection involving severe animal suffering as may prove to come within the scope of the existing law, and so to bring the matter prominently before the public eye; 3. Should it be found that grounds for such prosecutions are rarely to be obtained, owing to the secrecy with which vivisections are usually performed, or that, when undertaken, the state of the law renders them ineffectual, it may then be considered whether a Bill should not be introduced into Parliament making the publication of any cruel experiment in a scientific journal or other work a legal ground for the prosecution of the publisher, and thus throw upon the operator the onus of justifying the act. In view of the ambition for scientific notoriety, which may be deemed a not insignificant motive for the performance of many of these experiments, it is believed that this provision would be eminently effective; 4. If a Bill on the subject were found advisable, it might properly contain other provisions, such as, 1, the prohibition of all painful experiments on animals, except in authorised laboratories and by registered persons, whose experiments should be also registered as to number, nature, and purpose; 2, the absolute prohibition of painful experiments as illustrations of lectures; and, 3, the extension to three months of the interval of a single month now allowed by law for the prosecution of cruelty to animals after the commission of the offence.

The memorial, which was issued, we believe, in blank from the offices of the Society, now returns to it adorned by several hundreds of signatures of very distinguished persons. Statements so reckless and sensational naturally excite the ordinary feelings of humanity. It is improbable that the facts can now be adequately ascertained, except by parliamentary inquiry. We have already discussed the subject at some length, and refer to it in another column to-day. But the cloud of misrepresentation and calumny which has now gathered round it can only be dispelled by impartial inquiry. We are quite inclined to believe, with the *Times*, that, for the purpose of enlightening the mind and easing the conscience of those who have lightly accepted as facts the statements to which their signatures have been obtained, it is desirable that a Select Committee of the House of Commons should take evidence. We have no fear whatever of the results. Science and humanity must always benefit by impartial investigation. It must be remembered that "vivisections" form a very small part of physiological investigation and experimentation on animals, and that a majority of all operations are conducted under the influence of anæsthetics.

[FROM OUR OWN CORRESPONDENT.]

Lead in Aërated Waters.—*Jaborandi.*—*Requests to the Royal Infirmary.*—*Gas Explosion.*—*Royal Medical Society.*—*Hospital for Incurables.*—*Summer Lectures.*

At a meeting of the North British Branch of the Pharmaceutical Society, recently held in the society's rooms here, Dr. Stevenson Macadam read an important paper in connexion with the much debated question of the presence of lead in aërated waters. After mentioning that, in 1871, when he first took up the subject, he had made out that hard waters had a greater power of action over lead than soft waters, he gave a general description of the apparatus used in the manufacture of the aërated waters. He thought it of the greatest importance that the gas-holders should not be made of any material containing even a trace of lead in its composition, as he had found that the mere pouring

of water from a bottle into a lead pipe, and back again, caused a contamination, varying from one-twentieth of a grain per gallon in soda-water, to one-half per grain per gallon in lemonade; while if the waters were allowed to remain in the lead pipes for an hour, the amount of lead found would rise to two grains per gallon in soda-water, and ten grains in lemonade. The lead which contaminates, as the manufacture is at present carried on, is generally in the solder, as pipes of pure tin are easily obtainable. In samples sent him, he had discovered one grain per gallon in lemonade, and less in the other waters. At the same time, he had ascertained the further curious fact that the oil of lemons used for the lemonade generally contained quantities of lead, owing to the fact that the vessels in which the oil was stored were not free from that metal.

The new drug *jaborandi*, which is exciting much interest in Paris and London, has only been obtainable in very small quantities here. However, Dr. Craig was fortunate enough to get a small supply, and made some experiments upon himself, which fully established the value and power of this agent as a sialagogue and sudorific. He is still engaged in investigating the matter, but there appears to be much difficulty in getting hold of the drug in any quantity.

At an adjourned meeting of the contributors of the Royal Infirmary, held last week, an important alteration was made in the bye-laws regulating the use of bequests for the general purposes of the institution. Hitherto it has been the rule to treat all legacies of more than £100 in value as capital, and to invest them as such; but, in consequence of the ordinary income having been for some years past insufficient to meet the ordinary expenditure, it has been determined that henceforth all legacies under £500 shall be used as ordinary income. With regard to the subject which created so much unpleasant discussion, and even threats of an appeal to the law, at the original meeting, namely, the method of voting for the election of managers, it was decided to summon a special meeting to deal with it, as it was held to be incompetent to make an alteration of that kind at an adjourned meeting.

A somewhat serious gas-explosion took place a few days ago in a poor district of Edinburgh, the cause of which was unusual and unsatisfactory. For some days the family of the sufferers by the accident had been complaining of an escape of gas; but the place of leakage had not been discovered, when, while they were at dinner, the explosion took place in the room in which they were sitting, and one man had a leg broken. It was found that the gas escaped from a large pipe into the drain, which runs side by side with it, from the sink of the kitchen into the main road; and that the gas had travelled up the sink and been ignited by the fire. This looks very much as if other gases could travel up the same way, and shows a serious want of proper trapping or other protection against sewer-poisoning.

The Royal Medical Society is in a very flourishing condition this winter, and has had an accession to its strength of nearly forty new members. This is a very satisfactory state of things to those who believe, as every one who has taken much part in its proceedings does believe, that it is one of the most valuable agents in the curriculum of medical education which we possess.

The great bazaar in aid of the intended Hospital for Incurables was held last week, and was a great success. It was the largest affair of the kind which has been got up in Edinburgh for many years, and had the support and personal assistance of most of the nobility and leading families in the neighbourhood. The sum realised is a little over £5,000. When all expenses have been deducted—and they were unusually heavy, from the extent to which the advertising was carried—there will be a surplus to go to the fund of about £4,200.

Our courses of lectures next summer promise to be unusually interesting, as, in addition to having Professor Huxley to discourse upon Natural History, a course of Medical Physics is announced by Professor Tait, in which those points and subjects in natural philosophy which have a special bearing on the practice of medicine will be thoroughly expounded. The course supplies a long felt want, and, in the hands of so thoroughly competent a teacher and so excellent a lecturer as Professor Tait, will be of the highest value.

MEMORIAL WINDOW.—The well-proportioned wheel window in the front of the Chapel-in-the-Field, Norwich, has just been filled with Munich painted glass. As is recorded in an inscription, it is "In loving memory of Charles Mendis Gibson". January 12th, 1874, the date of Mr. Gibson's death, is added to the inscription. The window is placed in the chapel by his daughter, Miss Gibson. The design is floral, lilies and passion-flowers alternating in the wheel, and clusters of grapes in the outer portions of the light. The colours are very rich, and the workmanship most artistic. The work was executed by Messrs. Mayers and Co. of Munich.

ASSOCIATION INTELLIGENCE.

NORTH WALES BRANCH.

THE intermediate meeting of this Branch will be held at the Castle Hotel, Conway, on Tuesday, February 10th, at 12.30 P.M.; THOS. E. JONES, Esq., President, in the Chair.

Dinner at 3.30 P.M.

T. EYTON JONES, *Honorary Secretary, pro tem.*
Wrexham, January 19th, 1875.

PROCEEDINGS OF THE COMMITTEE OF COUNCIL.

At a meeting of the Committee of Council, held at the office of the Association, on January 14th, 1875—present, Mr. G. Southam (President of the Council), in the chair; Dr. Falconer (Treasurer), Mr. Alfred Baker, Dr. Bastian, Mr. Callender, F.R.S., Dr. A. Carpenter (Croydon), Dr. R. Farquharson, Mr. Reginald Harrison, Mr. F. E. Manby, Dr. Parsons, Dr. F. Sibson, F.R.S., Dr. Smart, C.B., Mr. Heckstall Smith, Dr. Steele, Dr. Wade, Dr. E. Waters (Chester), Mr. C. G. Wheelhouse, and Dr. E. Wilkinson.

Read letters of apology for non-attendance from Dr. Copeman and Dr. E. L. Fox.

The minutes of the last meeting were read and found correct.

Resolved—That those whose names appear in the circular calling the meeting be and they are hereby elected Members of the British Medical Association.

Resolved—That the Minutes of the Journal and Finance Committee of this date be approved and the recommendations carried into effect.

Resolved—That the Minutes of the Scientific Grants Committee be approved and the recommendations carried into effect.

Resolved—That the Scientific Grants Committee be authorised to appropriate the balance of £35 of the grant of £200 according to the terms of the resolution read.

Read communication from Norwich, viz.:

The following resolution has been passed by the Local Executive Committee of the Meeting of the British Medical Association in Norwich, in August 1874:

"The Local Executive Committee, acting for the Annual Meeting of the British Medical Association at Norwich, in August last, maintain that the invitation to M. Magnan was justifiable. They believe that the repetition in England of an experiment calculated to throw light not only on the effects of a dangerous dietetic agent, but also on the obscure pathology of convulsive nervous disease, was advisable, remembering that, by similar experiments assisted by money grants from the Association, an important advance in therapeutical knowledge has been recently established. Whether, however, the Committee acted wisely or not in granting M. Magnan the opportunity he requested, they cannot refrain from expressing their surprise and regret that Sir W. Fergusson, the late President of the Association, and Mr. Tufnell, should have lent the weight of their influence in aiding a criminal prosecution against five gentlemen, who were not only professional brethren, but four of whom were simply acting as Secretaries on behalf of the British Medical Association."

Resolved—That the Committee of Council sympathises with the Honorary Secretaries of the Norwich Meeting, and approves the action they have taken with respect to the recent discussion on Vivisection; that it desires to congratulate those gentlemen on the result of the trial arising out of that discussion; and recommends that the expense to which they have been put in defending themselves be paid out of the funds of the Association.

Read Minutes of Subcommittee appointed to consider Dr. McQuibban's case, and Report, of which latter the following is a copy:

Resolved—That the Subcommittee, having carefully considered the case of Dr. MacQuibban, as referred to them by the Committee of Council in Minute 24, beg to report that they fail to find that there is any evidence that Dr. MacQuibban was engaged as Military Surgeon; but some colour was no doubt given to the idea by the letter from Dr. Grant, naming Dr. MacQuibban as his substitute, and in addressing Dr. MacQuibban as Surgeon to the Aberdeenshire Militia. The Subcommittee cannot, however, pass over the fact, that the pay of civil practitioners engaged to perform the duties of Military Surgeon is absolutely inadequate, and the Subcommittee urge upon the Committee of Council the necessity of taking steps to represent to the authorities the unfairness of the regulations to Civil Surgeons, and the degrading effect of such a scale of remuneration.

Resolved—That the Minutes and Report of the Subcommittee appointed to consider Dr. MacQuibban's case in accordance with Minute

No. 24 be approved, and the Committee reappointed to consider and report upon the best way of bringing the matter before the proper authorities.

The Report of the Committee appointed at the Annual Meeting in London, August 1873, to consider the best means of providing for an adequate qualification in State Medicine for all Public Medical Officers, and referred to the consideration of the Committee of Council at the last Annual Meeting, held in Norwich, August 1874, was then considered.

Resolved—That Dr. Carpenter, Mr. Wheelhouse, and Mr. Callender be a Subcommittee to advise the Committee of Council upon the matter.

Resolved—That the consideration of the American letters be postponed.

The Laws of the South of Ireland Branch having been considered, it was

Resolved—That the laws of the South of Ireland Branch be approved and the Branch recognised.

Resolved—That the Committee of Council desire to congratulate the members of the South of Ireland Branch upon the formation of the first Irish Branch of the British Medical Association, and trust that it will be the means of causing a great increase of the Association in Ireland; and that the thanks of the Committee of Council are due and are hereby given to Dr. Macnaughten Jones and others for their exertions on behalf of the movement.

Resolved—That the Subcommittee appointed in November last be re-appointed to consider and form the by-laws for the government of the Association; viz., the President of the Council, the Treasurer, Dr. Steele, Mr. Husband, Mr. Wheelhouse, Mr. Nicholson.

Resolved—That the consideration of the alteration of the Aberdeen Branch be deferred.

Resolved—That the alteration of the name of the Northern Branch to the Northern Counties of England Branch be approved and confirmed.

CORRESPONDENCE.

THE HAMPESTEAD HOSPITAL QUESTION.

SIR,—I think it is an old saying, "There is seldom smoke without fire", and so with public alarm there is generally a foundation. In the case of a panic arising from a proposal to erect a fever-hospital in a certain locality, what are the grounds for alarm? The building, if erected, would be for the reception of patients suffering from infectious diseases, and who could therefore impart infection. Their removal from their homes would be more with a view of preventing the spread of infection in households than of bestowing personal benefit, for the statistics of fever-hospitals present a dark picture, not only as regards the patients, but also the attendants. The reason assigned for this is, that several patients are placed together in a ward, that infection becomes intensified, and disease assumes a severer type. Another source of danger is, that the walls of the ordinary fever hospital absorb infection, and thus, as it were, add fuel to the fire. So much respecting the danger to the inmates of the hospital. The residents in the immediate neighbourhood of such hospital naturally reason that the infected air proceeding from the building may possibly infect them. Whatever truth there may be in this reasoning, we are led to inquire, In what manner can a person be infected through the medium of the atmosphere? The generally received idea is, that the inhalation of air, holding in suspension either so called disease germs, or minute particles of infected animal matter thrown off from the patient's body, is the cause of infection. Concerning disease-germs we know very little; but we are aware that minute particles of desquamated cuticle in cases of scarlet fever and measles (two diseases often attended with serious and fatal complications) are carried hither and thither by air-currents, thus affording a ready means of spreading those diseases over an area of uncertain limit. Whether small-pox and typhoid fever are communicable through the air, there is less evidence to show; but I think, as a matter of precaution, they should be dealt with in a sanitary point of view, in the same manner as the two first-named diseases.

In treating on the subject of hospitals (wherever they may be built) for the reception of infectious diseases, two main points, therefore, present themselves for consideration; the welfare of the patients and other residents within such hospital, and the protection of the public in the immediate neighbourhood. To obtain the former, the building must be placed in a healthy locality on the side of a hill, having a southerly aspect, and should be so constructed that each patient shall be surrounded with air uncontaminated by himself, or by his fellow-patients, or by the building. This can be gained by isolating each patient in a

compartment made of non-absorbent materials, and having an inclined ceiling, the escape of foul air taking place at the summit of the incline, the ventilation being constant and complete. That the residents in the neighbourhood of such hospital may not be exposed to infection, the infected air from each compartment should undergo a purifying process by heat or by other means in its passage from the compartment to the outer air. These and other details of my mode of hospital construction have been published in the *BRITISH MEDICAL JOURNAL*. The conveyance of patients to the hospital could easily be managed, with safety to themselves and the public. A large van, built with non-absorbent materials, having a row of compartments on each side, and a passage up to the centre, should be sent around to collect the patients, and be eventually driven direct to the hospital, or be placed on a railway truck for the nearest station to the hospital. The inlet and outlet ventilators of each compartment in the van should be furnished with charcoal-filters, and the number of vans should be in proportion to the population.

A proposal has lately (December 26th) been made in the *Times* by Mr. Sydney Smirke, R.A., to have a floating hospital on the Thames for the reception of infectious cases from the metropolis, the patients to be conveyed thither in a steam-tender, specially fitted up for the purpose. Mr. Harry Leach, the medical officer of health for the Port of London, wrote, objecting to the scheme; his remarks, so far as they related to the vessel, being based on his experience of the old *Dreadnought*. About a year and a half since, I designed a sea-going hospital ship, embodying my published plan of construction. It has been approved of by many competent judges, and to such structure none of Mr. Leach's objections would be applicable.—I am, sir, yours obediently,

Plymouth, January 9th, 1875.

HENRY GREENWAY.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

A NICE POINT.—“The nicest point in the world,” to use the words of the chairman, arose upon an application, by a medical man, at the last meeting of the Honiton Board of Guardians, for payment of a midwifery fee. The district medical officer had been ordered to attend the case, but did not; and the applicant, being the nearest medical man, was fetched. The delivery took place shortly after midnight, when the appointment of the district medical officer, being yearly, terminated; and it was argued that he was not, therefore, in office until re-appointed. Under the circumstances the guardians voted ten shillings to the applicant.

MILITARY AND NAVAL MEDICAL SERVICES.

PROMOTIONS.—Surgeon-Major A. L. Adams, M.D., retiring on half-pay, to have the honorary rank of Deputy Surgeon-General.—Surgeon-Major J. Fayrer, C.S.I., Indian Army, to be Deputy Surgeon-General.

NAVAL MEDICAL SERVICE.

It is announced that, questions having arisen as to the right of naval medical officers to practise their profession on shore when borne on the books of one of Her Majesty's ships, the Admiralty has decided that, when a medical officer is on full-pay, he should confine his professional attendance to those placed under his charge officially, and should not seek to obtain a practice among the civil community. From what we know of our naval medical brethren, we feel that this decision of the Admiralty will be acquiesced in as generally fair in preventing officers on full-pay from entering into private practice ashore in the ports at home where they may happen to be stationed. It intimates, too, the principle, that the pay given by the State is in exchange for the whole time and professional labour of its medical *employés*. This is very different from the action of the last Government, that declined to interfere in the co-operative functions of the clerks in the War Office and Admiralty after working hours. But, in all those cases affecting ourselves, we believe that much more is gained by the sense of honour generally pervading the more secured ranks of our profession than by any departmental orders; and we have reason to know that very seldom is the feeling of mutual support invaded on either side.

As concerns private practice on foreign stations, we have always understood that it is a recognised practice of the army, from which many derive considerable emoluments; while, on the other hand, even there, where the value of medical knowledge is enhanced by the scarcity of practitioners, the regulations of the navy can be brought to prevent the profitable occupation of his spare time by the surgeon of a ship of war. This, we contend, is scarcely just to the medical officer or to the sick, who would willingly request his aid if they knew that they could with propriety offer its requital. Let us trust that this decision may not be carried to its logical conclusion, where advice is sought without prejudice to any settled private practitioner.

UNIVERSITY INTELLIGENCE.

UNIVERSITY OF CAMBRIDGE.

PROFESSOR HUMPHRY'S LECTURES.—The Professor of Anatomy gives notice that the Lectures on Anatomy and Physiology will be continued on Tuesdays, Thursdays, and Saturdays, at 1 P.M., in the New Museums. The Lectures on Practical Anatomy will be continued on Wednesdays and Fridays, at 9 A.M. There will be classes in the Easter Term for gentlemen who are preparing for the Second Examination for M.B. There will be classes in Osteology and Practical Histology in July and August.

UNIVERSITY OF EDINBURGH.

ADDITIONAL EXAMINERS FOR DEGREES IN MEDICINE.—At a recent meeting of the University Court, the following appointments of additional Examiners in Medicine were made under the regulations approved by Her Majesty, by order in Council of 6th August last:—With power of annual reappointment by the Court for three years—John Chiene, M.D.Ed., Lecturer on Surgery, to be Examiner on Anatomy; Angus Macdonald, M.D.Ed., Lecturer on Midwifery, to be Examiner on Midwifery; and James Dunsmure, M.D.Ed., formerly Surgeon to the Royal Infirmary, to be Examiner on Clinical Surgery. With power of annual reappointment by the Court for four years—Hugh Cleghorn, M.D.Ed., Stravithy, St. Andrew's, formerly Professor of Botany and Botanist to Government, Madras, to be Examiner on Botany; David Ferrier, M.D.Ed., Professor of Forensic Medicine, King's College, London, to be Examiner on Medical Jurisprudence. With power of annual reappointment by the Court for five years—James Dewar, F.R.S.E., Lecturer on Chemistry, Edinburgh, to be Examiner on Chemistry; Dyce Duckworth, M.D.Ed., Assistant-Physician to St. Bartholomew's Hospital, London, to be Examiner in Practice of Physic; and William McIntosh, M.D.Ed., Murthly, author of various works on zoology, to be Examiner on Natural History. With power of annual reappointment by the Court for six years—Joseph F. Payne, M.B.Oxon., Assistant-Physician to St. Thomas's Hospital, London, to be Examiner on Pathology; and Thomas R. Fraser, M.D.Ed., F.R.S.E., Medical Officer of Health for Mid-Cheshire, to be Examiner on Materia Medica. With power of annual reappointment by the Court for seven years—James Dunsmure, M.D., to be Examiner on Surgery; D. R. Haldane, M.D.Ed., Lecturer on Practice of Physic and on Clinical Medicine, to be Examiner on Clinical Medicine; and Arthur Gamgee, M.D.Ed., F.R.S.S. Lond. and Edin., Professor of Practical Physiology in Owens College, Manchester, to be Examiner on Institutes of Medicine.

DR. HENRY TIZARD has been presented with a handsome epergne, and an address, printed in gold on blue satin, and framed. On the base of the epergne is engraved, “Presented to Henry Tizard, Esq., M.D., by the brethren of the Loyal Excelsior Lodge of Odd Fellows, Weymouth (Poole District, M.U.) as a token of their respect and esteem for his valuable services to the Lodge, Christmas, 1874.” The address was as follows: “To Henry Tizard, Esq., M.D., J.P., Medical Officer of the Loyal Excelsior Lodge of Odd Fellows, Weymouth (Poole District) Manchester Unity. The Officers and Brethren of the Loyal Excelsior Lodge desire to thank you most heartily for your uniform kindness and attention to them, both in sickness and in health, during the long period that you have been connected with the lodge, and they beg you to accept this epergne (with this address), as a token of their great respect and esteem. The members of the lodge have great pleasure in wishing you and your family the compliments of the season, and they trust that you may be spared for many years to continue those services which you have discharged so faithfully and so well during the past. Christmas, 1874.”

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at a meeting of the Court of Examiners, on January 25th.

Messrs. Ernest W. Paul, Brixton; Robert Kains, Palace Road; Sydney Lloyd Smith, Brixton Road; William Makeig Jones, Blaenavon, Monmouthshire; Charles L. Webb, Bentley, Hants; Thomas Park, Greenwich; Frank de Leuchamp Collette, Guernsey; William I. Hughes, Carmarthen; Francis F. Frodribb, Upper Clapton; Arthur C. Haden, Sloane Street; and Ernest William H. Sall, Lancaster.

The following gentlemen were admitted members on January 26th.

Messrs. James Black, Highgate Road; Walter C. Morris, Barbadoes; William A. Stradling, Sloane Street; Marie Edouard Vallant, Charles Street, Portman Square; Henry Haggood, Eastbourne; Arthur E. Sargent, Belsize Park; Henry H. Clutton, Westminster; William B. Richardson, Leeds; Henry M. Sanjeon, Yeovil, Somerset; John J. E. V. Hamersmith, Alexander F. Hawkins, Blackrock, near Dublin; Evan M. Boddy, Camberwell Road; Francis Williamson, Durham Place, Chelsea; Thomas Walter Farron, Sunderland; Edward Shackfield Newton, Canbury Park; Ivor A. Lewis, Llantrissant, Glamorganshire; John Alfred Dearden, Douglas, Isle of Man; Francis Newsham, Oldham; George H. Koss, Hart Street, Bloomsbury; and Ernest C. Jackson, Harley Street.

The following gentlemen were admitted members on January 27th.

Messrs. Edward J. Adkins, Canonbury; V. L. H. Jones, Carmarthen; Edwin Lee, Leeds; Paul M. Chapman, Camden Park Road; Alfred George Buckland, L.S.A., Auckland, New Zealand; Clinton Thomas Dent, B.A. Cantab., Chesham Street; Herbert Duke, Clapham Road; Alfred Parks, West Bromwich; Charles Ferdinand Marks, M.D., Queen's University, Ireland, Dublin; Leonard Rudd, Kempsey, Worcester; Herbert Isambard Owen, B.A. Cantab., Gloucester Gardens; James Deighton Dixon, Gateshead; Walter Edmunds, B.A. Cantab., Hampstead; Robert Turner Hales, Holt, Norfolk; Friend Edward Streeten, Ealing, Middlesex; Frederick Worrell Friend, Payswater; Ernest F. Cooper, Canonbury; Edwin K. Hutton, Lever Street, St. Luke's; and Kenneth S. Wallis, Cambridge.

Twenty candidates out of the seventy-four examined having failed to acquit themselves to the satisfaction of the Court of Examiners, were referred to their studies for six months; and eight, having passed in surgery, will be admitted members of the College when qualified in medicine.

APOTHECARIES' HALL.—The following gentleman passed his examination in the science and practice of medicine, and received a certificate to practise, on Thursday, January 7th, 1875.

Orr, James William, Femberly, Bedford.

The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, January 21st, 1875.

Lewis, Joseph, Milborne Port, Somerset
Walker, Hyde Edwards, Broughton-in-Furness, Lancashire

The following gentleman also on the same day passed his primary professional examination.

Barrow, John, St. Bartholomew's Hospital

MEDICAL VACANCIES.

THE following vacancies are announced:—

ABBEYLEIN UNION—Apothecary.

ARMY MEDICAL DEPARTMENT—Surgeons. Applications to be made to the Director General of the Army Medical Department.

BARONY PAROCHIAL HOSPITAL, Barnhill, Glasgow—Dispenser.

BECKETT HOSPITAL AND DISPENSARY, Barnsley—House-Surgeon. Salary, £140 per annum, with furnished rooms, gas, and coals.

BIRMINGHAM AND MIDLAND FREE HOSPITAL FOR SICK CHILDREN—Acting and extra-Acting Physicians. Applications not later than February 1st.

BLACKBURN UNION—Medical Officer for the Harwood District. Salary, £25 per annum.

BRENTFORD UNION—Medical Officer for the Ninth District. Salary, £30 per annum.

BROMSGROVE UNION—Medical Officer for the Workhouse and the Bromsgrove District. Salary, £30 and £60 per annum, respectively.

DERBYSHIRE GENERAL INFIRMARY—Assistant House-Surgeon. Board, lodging, and washing, but no salary. Applications to Secretary.

FIMSWORTH—Certifying Factory Surgeon.

ESSEX LUNATIC ASYLUM—Second Assistant Medical Officer and Dispenser.

Salary, £100 per annum, with board, lodging, and washing.

FLAN MILLS FRIENDLY SOCIETY—Medical Officer. Salary, £110 per annum.

Applications to A. M. Keeman, 7, Hinton Square, Johnstone, N.B.

GRANTHAM UNION—Medical Officer for the Ropsley District. Salary, £60 per annum.

HARDINGSTONE UNION—Medical Officer for the Bralford District. Salary, £45 per annum.

HARRIS, Parochial Board of—Surgeon. Salary, £60 per annum, including vaccination and medicine for the poor. The gentleman elected will get £90 per annum for attending the ratepayers and cottages within South Harris. Applications to be made to the Chairman of the Parochial Board of Harris.

HEADINGTON UNION—Medical Officer for the Wheatley District. Salary, £70 per annum.

HENDON UNION—Medical Officer for the Willesden District. Salary, £40 per annum.

HOSPITAL FOR WOMEN, Soho Square—Surgeon and Assistant Physician.

HULL GENERAL INFIRMARY—Dispenser. Salary, £75 to £100 per annum.

Election will take place on the 28th instant.

INDIAN MEDICAL SERVICE—Twenty appointments as Surgeon. Examination in February 1875.

KILCHRENNAN AND DALRYMPLIE, Parochial Board of—Medical Officer. Salary, £60 per annum. Applications, on or before the 30th instant, to W. J. B.

Martin, Kircubbin, Lochgilphead.

LEEK UNION—Medical Officer for the Endon District. Salary, £20 per annum.

LICHEFIELD UNION—Medical Officer for the Alrewas District. Salary, £35 per annum.

MORVEN, Parish of, Argyllshire—Medical Officer. Salary, £100 per annum.

Applications to H. A. Fraser, Morven, N.B.

NORTHERN COUNTIES HOSPITAL FOR INCURABLES, Manchester—Dispenser. Applications on or before the 31st instant.

NORTH WALES COUNTIES LUNATIC ASYLUM—Assistant Medical Officer.

Salary, £100 per annum, with board, washing, and lodging. Applications to be made on or before February 17th.

PAISLEY INFIRMARY—House Surgeon. Salary, £80 per annum, with board and lodging. Apply to W. Hodge, Writer, Paisley, on or before February 6th.

POPLAR AND STEPNEY SICK ASYLUM DISTRICT—Assistant Medical Officer to the Asylum.

REDDITCH AND DISTRICT MEDICAL ASSOCIATION—Medical Officer.

Salary, £150 per annum, with fees and unfurnished house.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City Road—Physician. Applications to be made on or before February 15th.

ROYAL INFIRMARY FOR WOMEN AND CHILDREN, Waterloo Bridge Road—Physician.

SAFFRON WALDEN UNION—Medical Officer for the Seventh District.

Salary, £86 per annum.

ST. GEORGE'S AND ST. JAMES'S DISPENSARY—Honorary Accoucheurs.

Applications on the 28th instant.

ST. LUKE'S HOSPITAL FOR LUNATICS—Second Clinical Assistant. Board and furnished apartments.

ST. MARY'S HOSPITAL, Paddington—Resident Registrar. Salary, £100 per annum, with board and residence.

ST. MARY'S HOSPITAL—Resident Registrar. Salary, £100 per annum, with board and lodging.

ST. MARY'S HOSPITAL MEDICAL SCHOOL—Medical Tutor. Applications to be made on or before February 1st.

SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY—House-Surgeon.

Salary, £100 per annum, with board, lodging, gas, and washing.

SMALLBURGH UNION—Medical Officer for the Ludham District. Salary, £52 14 per annum.

STRATFORD-ON-AVON UNION—Medical Officer for the Welford District and Workhouse. Salary, £50 per annum.

THINGOE UNION—Medical Officer for the Seventh District.

TYNEMOUTH UNION—Vaccination Officer.

ULVERSTONE UNION—Medical Officer for the Hawkshead District. Salary, £20 per annum.

UNIVERSITY COLLEGE HOSPITAL—Resident Medical Officer. Applications not later than February 13th.

UNIVERSITY OF EDINBURGH—Additional Examiner in Medicine.

WEST WARD UNION—Medical Officer for the Patterdale District.

WISBECH UNION—Medical Officer for the Third District. Salary, £30 per annum.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

BEACH, Fletcher, M.B., appointed Medical Superintendent of the Clapton Asylum for Idiots, London.

BROOKHOUSE, Joseph O., M.D., appointed Physician to the General Hospital, Nottingham, *vice* W. T. Robertson, M.D., resigned.

BROWN, Alfred G., M.R.C.S. Eng., appointed Surgeon to the Surrey Dispensary.

BROWN, William J., M.B., appointed Assistant Medical Officer to the Borough Lunatic Asylum, Newcastle-on-Tyne, *vice* E. G. Levinge, M.B., resigned.

BRENTON, Thomas Lauder, M.D., F.R.S., appointed Assistant-Physician to St. Bartholomew's Hospital.

BROWN, Herbert G., L.R.C.P., appointed Surgeon to the Worcester Ophthalmic Institution.

BERTONSHAW, Henry, L.S.A., appointed House-Surgeon to the North-Eastern Hospital for Children, *vice* G. Brown, M.R.C.S. Eng., resigned.

CHURCH, William S., M.D., appointed Physician to St. Bartholomew's Hospital, *vice* F. Harris, M.D., resigned.

FIRTH, Charles, M.B., appointed Assistant-Surgeon to the Norwich Lying-in Charity, *vice* H. Ward, M.R.C.S. Eng., resigned.

FITZGIBBON, Henry, M.D., appointed Surgeon to the City of Dublin Hospital, *vice* J. Tufnell, F.R.C.S.I., resigned and appointed Consulting Surgeon.

GIBSON, Robert E., M.R.C.S. Eng., appointed Surgeon to the Norwich Lying-in Charity, *vice* T. W. Crosse, F.R.C.S. Eng., resigned.

GRINFIELD-COWELL, John E., L.R.C.P.L., appointed Medical Officer to the Worthing Infirmary, *vice* J. Goldsmith, M.D., resigned.

HART, Philip N., M.B., appointed House-Surgeon to Queen Charlotte's Lying-in Hospital.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.

BIRTH.

SWAN.—On January 24th, at Northleach, Gloucestershire, the wife of *R. Jocelyn Swan, M.R.C.S., etc., of a son.

MARRIAGE.

SIMPSON-BRUCE.—On January 21st, at Keig, Aberdeenshire, by the Rev. Duncan Campbell, B.D., James Simpson, M.D., of Tullynessle and Forbes, to Mary Barr, daughter of Alexander Bruce, Esq.

OPERATION DAYS AT THE HOSPITALS.

MONDAYMetropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

TUESDAYGuy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

WEDNESDAY ..St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

THURSDAYSt. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.

FRIDAYRoyal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.

SATURDAYSt. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M.—Royal Free, 9 A.M. and 2 P.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY.—Medical Society of London, 8.30 P.M. Mr. Maunders's Third Lettomanian Lecture, "On Ligation of an Artery to arrest Traumatic Inflammation".—Odontological Society, 8 P.M.

TUESDAY.—Pathological Society of London, 8.30 P.M. Mr. Howard Marsh: Elongation of Bones of Lower Extremity in a Case of Diseased Knee (living specimen). Mr. Lawson: Sarcoma of Sclerotic. Dr. Hoggan: Microscopical Specimens of Melanoid Sarcoma in a Cod. Dr. Hoggan: Microscopical Specimens of Cancer. Dr. Dowse: Invaginated Intestine. Dr. Dowse: Syphilitic Disease of Rectum. Dr. Pye-Smith: Enlarged Liver and Spleen without Leukæmia. Dr. Pye-Smith: Hemorrhagic Gut. Dr. Pearson: Cancerous Breast and Liver. Mr. Cripps: Fatty Degeneration of Muscles of Thigh. Dr. Greenfield: Contraction of Coronary Arteries. Dr. Greenfield: Obstruction of Renal Artery. Dr. Greenfield: Fibroid Disease of Heart. Mr. Butlin: Fatty Tumour removed during Herniotomy. Mr. Hutchinson: Teeth met with in Zonular Cataract. Mr. Knowsley Thornton: Melanotic Sarcoma.

WEDNESDAY.—Obstetrical Society of London, 8 P.M. Inaugural Address by the President, Dr. Priestley; Dr. Braxton Hicks, "Three Cases of Cephalotripsy, with Casts of the Heads"; Dr. Oswald, "Notes of a Case of Suppurating Tumour of the Left Ovary, with specimen"; Mr. Ashburton Thompson, "On Zinc Phosphate in Amenorrhœa"; Dr. Trestrail, "On the Treatment of Rigid Pericæum, and the avoidance of its Rupture"; Dr. Liebmán (of Trieste), "Clinical Notes on the Early Course of Cancer of the Cervix Uteri"; and other communications.—Royal Microscopical Society, 8 P.M. Anniversary Meeting.

THURSDAY.—Harveian Society of London, 7.15 P.M.: Council Meeting, 8 P.M.; Dr. W. H. Day, "On Cerebral Complications in the Typhoid Fever of Children".

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with *Duplicate Copies*.

AUTHORS desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor: those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

THE CONTAGIOUS DISEASES ACTS.

DR. CAMERON of Liverpool writes to inform us that if the entire staff of the Royal Southern Hospital, ten in number, only three have signed the memorial in favour of the Contagious Diseases Acts. Of about three hundred and twenty-two practitioners in Liverpool, one hundred and seventy-four have, we believe, signed the memorial. Of course, a good many are neutral, a good many uninterested, and some unfavourable.

M.B. EDIN.—The right of Bachelors of Medicine to assume the title of Doctor is at least doubtful, although courtesy habitually grants it to them. The Regulations of the University of London contain a distinct statement on this matter; viz., "The Senate desire it to be understood that Bachelors of Medicine of the University of London have no right, as such, to assume the title of Doctor of Medicine".

NOTICE TO ADVERTISERS.—Advertisements for insertion in the BRITISH MEDICAL JOURNAL, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than *Thursday*, twelve o'clock.

POISONING BY NITROUS OXIDE.

SIR.—My brother is a chemist in an alkali manufactory, and he has to work a great deal in a room impregnated with the fumes of nitric oxide. He frequently becomes severely poisoned by this atmosphere. He is anxious to learn what methods, or what antidotes, to adopt in order to relieve himself when in this state: because he finds that none of the medical men in his neighbourhood know much, if anything at all, about this kind of poisoning. He has found that leaving the room and keeping in fresh air palliates the symptoms, but it is a long time before the effects pass away. Will some of your readers kindly help him? Will they also state whether the inhalation of ether or ammonia would be of any service?

January 21st, 1875.

I am, etc., M.R.C.S.

DR. MURPHY.—It is an old saying, that a warm October is supposed to predict a cold February; but

"If there's ice in November that will bear a duck."

There'll be nothing after but sludge and muck."

In April, say the Milanese, it is a fine time to lie in bed. May is a general favourite, although

"Come she early, or come she late,

She'll make the cow to quake."

A QUESTION ON CLUE-PRACTICE.

SIR.—Is a man suffering from tertiary syphilis (rupia) entitled to the benefit of his club (Foresters)? The primary disease occurred after he had become a member, but as long as ten years ago. My own opinion is that, in justice, he should be, or one who suffers from acquired gout should not.—Yours faithfully,

January 27th, 1875.

B. S.

"In the supposed case, the club member is certainly entitled to treatment."

DR. J. A. P. (Manchester).—The prizes offered by the Royal College of Surgeons are open for competition amongst Fellows and Members of the College, not others. The subject for the Jacksonian Prize for the present year is "The Use of the Galvano-Cautery in the Removal of Morbid Growths", the essays for which must be delivered before Christmas-day next. The subject for the College Triennial Prize is "The Radicles of the Lymphatic System in Relation to the External and Internal Surfaces of the Body". The prize for the latter is either a gold medal of the value of fifty guineas, or a bronze medal (the John Hunter, and fifty pounds in cash.

AN APPEAL.

SIR.—I beg to appeal to the medical world for a small donation in behalf of myself and three little children, the eldest only three years and a half old. My husband's death is the cause of my pleading. He expired in the County Asylum, Prestwich, on December 8th, 1874, aged 29, having been confined there since April 2nd. My husband had not attended to his practice for some time previously. He told his patients he was going on a tour, and they must call in some one else. The very day he was taken to the Asylum he parted with nearly all the furniture for a quarter the value; therefore every chance of making a little money was taken from me, and we have been left quite unprovided for. The day my husband was taken we had no money in the house, and he only a few stamps in his pocket. A neighbour, hearing how destitute we were left, kindly assisted me; and in a few days some of the medical gentlemen in Bolton-le-Moors, where my husband practised, gave me a few pounds. The facts can be attested by the signatures of the following gentlemen, of Bolton:—T. Garstang, M.R.C.S.; Robert Seftle, M.D.; John Holt, M.R.C.S.; Thomas F. Pickering, L.R.C.P.; Edward Sunderland, M.R.C.S.; Robert Patrick, M.R.C.S.; George Howarth, L.R.C.P.; F. B. Mallett, M.D.; Thomas Derham, M.D.; James Mackintosh, M.D.; Fredk. Waterhouse, L.R.C.P.; James Dorrian; H. Hutton; John Livy, M.D.; James Hall, M.B.; J. E. Scowcroft, L.R.C.P.; Chas. Rothwell, M.R.C.S.; John Redmayne, M.R.C.S.; Henry Powell, Vicar of Bolton; John Stott, Lecturer and Curate, Parish Church, Bolton-le-Moors; J. Bins Southam; R. F. Snape, F.R.C.S.; E. M. Garstang, M.R.C.S.—Yours very faithfully,

CHARLOTTE M. NUTT.

15, Askew Road, Shepherd's Bush, London, January 1875.

MR. R. J. GRIFFITH (Punjab).—Your letter shall be attended to; but all business communications should be addressed to the General Secretary, and not to the Editor.

EXAMINATIONS.

An important change will be seen in the following questions recently submitted to the candidates at the primary examination for the diploma of Membership of the Royal College of Surgeons. 1. What evidence exists of the influence of the nervous system on the functions of secretion and excretion? Explain how such influence may be exerted; and illustrate the subject by examples. 2. How much oxygen is consumed by a healthy adult person, under ordinary circumstances, daily? What are its principal purposes in the system? and in what forms is it chiefly eliminated? 3. Describe the diaphragm, its attachments, relations, and action. 4. Describe the thyroid and cricoid cartilages. Enumerate the muscles connected with them; and state the exact attachment of each. 5. Mention in order, from before backwards, the several structures which are in contact with the first rib. 6. Mention the structures exposed on removal of the palmar fascia; and describe their relative position. Candidates were required to answer four (including one of the first two) out of the six questions. Answers to less than six questions were not received before half past three o'clock.

G. L. R.—From inquiries made, we find you have passed the preliminary examination in Arts, and can therefore commence your professional studies at once at St. Mary's Hospital, and thus save half a session. All the candidates, so far as we have had announcements sent to them.

OUT-PATIENTS AT THE SOHO HOSPITAL.

SIR.—In a recent article in the *Daily News*, the following information is vouchsafed. "The out-patients of this hospital are very numerous, and Dr. Heywood-Smith and his colleagues are sometimes seven hours in disposing of them." Attention has already been drawn in your columns to the abuse of the out-patient departments in this and other hospitals. As Sir R. Alcock, an able member of the Charity Organisation Society, is, I believe, also now an active member of the Soho Hospital, we may hope that he will give his attention to weeding the out-patients. I do not know what may be the meaning of the phrase "Dr. Heywood-Smith and his colleagues". If Dr. Smith have any colleagues in disposing of the out-patients, I suppose they are not ashamed of their names being known, and they might as well be given.—I am, sir, yours, etc.,

N. L.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

MEDICAL DEGREES AND TITLES.

SIR,—Your correspondent in the JOURNAL of the 9th instant, who signs himself "Igualdad ante la lei," I fear knows very little about the Universities when he says that Oxford and Cambridge "deservedly stand first," because the "holders of the above degree are gentlemen, and, to a certain extent, classical scholars." Now, sir, why the epithet "gentlemen" should be exclusively applied to men from Oxford and Cambridge, I cannot imagine. As to their being, "to a certain extent classical scholars," if your correspondent had taken the trouble to compare the Dublin course with the Oxford or Cambridge course for the degree of B.A. (it is necessary in all three Universities to have the B.A. before the M.B. or M.D. can be obtained), he will find that the Dublin course embraces a larger number of subjects, and contains a long list of classical authors. In Oxford, classics predominate; in Cambridge, mathematics; so his assertion is not applicable to the latter University. I of course am only alluding to men who merely go through the course for the B.A., which the majority of men destined for our profession only do. I therefore think we are quite as much entitled to be, "to a certain extent, classical scholars." In Edinburgh, I believe it is not necessary to be a graduate in arts in order to obtain the M.D., so she would be excluded from the above question, only as regards her *alumni* being "classical scholars."—I am, sir, your obedient servant.

A "B.A. AND M.B." OF TRINITY COLLEGE, DUBLIN.

January 10th, 1875.

SIR,—I read with great interest your able article in the JOURNAL of the 20th ult., and, having followed from the first the controversy which has of late been carried on in your columns, I am led to be of your way of thinking on many of the points therein discussed. It seems to me, however, that there is an unnecessarily vast amount of jealousy in the breasts of those who would be unfortunate practitioners who do not possess the M.D. degree. If, as some one of them states, the sucking graduate is so much to be despised, why do they so anxiously covet his degree? One gentleman signing himself "L.K.Q.C.P." seems to have become so much bewildered as to what he is, that he asks to be enlightened on the subject by some "energetic M.D." I do not profess to be such, but should like to ask Mr. L.K.Q.C.P. of what he is a Doctor. Because he is a Licentiate of the College of Physicians, as well as Surgeons, he declares that if he be not a doctor, by the same token, then, he cannot be a surgeon. This seems to me to be very like a man arguing that because he is house-surgeon to a hospital (being L.R.C.P. and M.R.C.S.), therefore he is a physician to that hospital as well, or nothing at all. It is almost a pity but that some of the aspirants to M.D. degrees could be transplanted to Birmingham, for there they would soon become sickened of their high and mighty ambition. In that "great centre of advancement," you have "Dr. Smith" (the chemist); "Mr. Jones, physician" (M.D., F.R.C.P.); and last, but not least, "Mr. Robinson, physician" (a general practitioner, holding a surgeon's appointment at the Infirmary, taking physicians' fees for medical cases, and delighting in being considered a physician). How would this suit them?

Now let us see what is the result of granting degrees to men over forty. They are general practitioners all their lives till that time; they go to St. Andrew's, come home with their M.D., have the fact announced in the newspapers, and for ever after are looked up to as men superior to their fellows, as "having taken their physician's degree." Far higher do they stand, indeed, in the eyes of the general public than any man who, having worked hard, and having been fortunate enough to have obtained a university education and degree, starts in the neighbourhood, and can obtain no better title than "Mister" from his patients. Let us all be styled "Dr." if you like, but do not let the general public be led astray with the notion that, because a man goes up and gets his M.D. late in life, he is a superior being in any way. What do we find some L.R.C.P.s doing with the deluded public? Why, endeavouring as best he can to impress upon them that he is better than "Mr. So-and-so, the M.D." "I am a physician," says he, "and that is more than he is." No man, I take it, ought to style himself physician unless he practise as such, and then he ought to be more than a Licentiate. A man is not esteemed any the less by his patients because he is not an M.D.; then why should there be such a desire, on the part of the non-M.D.s for the title of Dr., unless it be that there is a vein of jealousy existing, which, to say the least of it, is childish—a vain conceit? They envy their younger brethren, and, fearing lest they should obtain any patients, would do anything to have the world think that they were not equal to themselves. This is a view of the matter which, I think, has not been put forth, and a reason, I consider, why the elder practitioner should not be admitted to the M.D. degree without residence or stricter examination. I do not see that the Universities are to blame for the matter; what ought to be objected to are the Colleges of Physicians which grant Licentiates' diplomas, and allow their holders to consider themselves qualified more than general practitioners—I mean the old-fashioned "College and Hall" men.

For some time back I have come to the conclusion that so long as there are different qualifications granted, so will there always be jealousy extant; for what, I say, is to hinder M.D.s, by university education, from labelling themselves "M.D. Lond.," "M.D. Ed.," and so forth; and will they not, forsooth, always be considered (amongst the profession at any rate) better than M.D.s, the after birth?

With many apologies for this already too long communication, I subscribe myself, in all humbleness, yours,

L. M.

January 9th, 1875.

SIR,—It appears the thread-bare, and, as I thought, the worn-out, controversy about medical titles has again found a lodgment in the columns of the JOURNAL. I fully expected this much vexed question had been with long cremated; but it appears that, like the mythological phoenix of old, it has again risen from its own ashes, and assumed a lively and vigorous state of existence. It appears, to my mind, a piece of foolish absurdity and waste of valuable time squabbling about "medical titles." It is not what a man professes to be, but what he is. What do the public care about titles? They designate all who practise medicine or surgery, legally or otherwise, "Doctors." The common apothecary, the homoeopathic or other quack, the village "bone-setter," and last, not least, the pompous kid gloved and dashing unqualified medical assistant, all come under this appellation by an unscrupulous world, as well as the most learned and orthodox practitioner in Christendom. I do feel ashamed at some of my brethren wasting their valuable time in so puerile and contemptible an occupation, by taking up a subject that has virtually no interest in itself, in the minds of those whose higher and more laudable aims are the advancement of professional enterprise and the general benefit of humanity. If, instead of indulging their *caecities aridendi*, they would employ their talent

and influence to a better and more laudable purpose, it would redound more to their credit. There are numerous subjects on which the mind could dwell and experience develop, and this would be more productive of permanent good than squabbling about medical titles. To take up the language of our facetious "Mid-diesex" friend, if a fully legally qualified and registered practitioner be not a Doctor, what is he? a "baker or a tinker?" Would it not have been better had our opponents commenced a tirade upon the advertising quacks, who do not scruple to affix "Dr." to their names, instead of attacking legitimate practitioners in the way they have done? Are they more contemptible in the eyes of our *confidés* than those vile scoundrels who assume a position to which they have no legitimate right, and who are allowed to glory in their shame without the least attempt at interference? Let our University men who wish to lay claim to the honoured and distinctive appellation of M.D. or Dr., commence their onslaught on these pseudo-practitioners, and exterminate the whole race, before they venture to attack their equals in point of professional knowledge and position.—I am, yours respectfully,

A REGISTERED PRACTITIONER.

January 1875.

On Winter Cough, Catarrh, Bronchitis, and Emphysema. By H. Dobell, M.D. London: J. and A. Churchill. 1875.

AN ADDRESS ON OBSTETRIC LITERATURE AND SCIENCE.

Delivered before the Obstetrical Society of London.

By W. O. PRIESTLEY, M.D., F.R.C.P.,
President of the Society.

GENTLEMEN,—In taking the Chair, which by your kind favour I occupy for the first time this evening, I am anxious to express my sincere thanks to the Society for according to me a position so distinguished.

When my nomination to the Presidency of the Obstetrical Society was first mooted, I confess I felt many misgivings as to my competence for such a responsibility. It is true that some twenty years occupied as an obstetric teacher and practitioner may give one a claim to be numbered among the seniors of the profession; but the pressure of other occupations, and considerations of health, have for a considerable period obliged me to abstain from attending the meetings of this and other societies, and consequently I am less familiar with the modes of procedure than some of our more eminent Fellows, who have "borne the burden and heat of the day", and who might justly look forward to the President's Chair as the reward of excellent service to the Society.

My objections on these points were overruled, and, when I understood that it was the earnest wish of the Council that I should be put in nomination, I could no longer hesitate to submit myself to the wish of the Society, and to accept what was so spontaneously offered. It remains for me to tender my acknowledgment of the honour conferred upon me, and to thank both the Council, who nominated, and the Fellows of the Society, who have ratified its selection. Whatever of diligence and of zeal may be required of your President, I shall do my utmost to bring to the discharge of the duties of this Chair, and, aided by our experienced secretaries, I may hope to conduce to a satisfactory dispatch of business, and a general advancement of the objects contemplated in the foundation of the Society.

Having been one of the original members—one of the small band who in 1858 met to consider the propriety of instituting an Obstetrical Society in London—I have watched with much interest its development from infancy to maturity, and the success it has achieved may well be a source of pride to its Fellows. There is, I believe, no parallel instance in the history of a medical society in this country of such rapid growth in so short a period as that which has taken place in the Obstetrical Society. In the short space of sixteen years, it has enrolled wellnigh 700 Fellows, and the annual recurrence of the *Transactions* testifies to the large number of active workers and contributors. The fact, indeed, has become apparent that the Society supplied a want which had previously been indefinitely felt by a large number of medical practitioners, and which only assumed the concrete when the Society was formed.

It has been said that every practitioner regards himself as an expert in obstetric practice, which perhaps is only another way of saying that most general practitioners have felt the tug and strain on their resources in midwifery practice, the necessity for immediate action in moments of peril, and that most have some victories to chronicle, some recollection of difficulties surmounted which have left perhaps more vivid impressions than in any other kind of practice. Be this as it may, the fact that by far the largest proportion of medical men in this country are engaged more or less in the practice of obstetrics, and in treating the diseases of women and children, affords a broad basis for the interest which is felt in a society whose object is to promote improvements in the obstetric art, and its influence permeates and pervades the mass of our medical brethren in proportion to the importance of the subject to them, and its bearings on their daily work.

Reviewing the history of the Society—young as it may be—I cannot doubt that it has done much good, and achieved something by way of advancing the science and art of obstetric medicine. The number and diversity of the contributions contained in the *Transactions*, the long record of pathological specimens, the exhaustive discussions on special topics, are all evidences of the zeal possessed both by town and country Fellows; and an appreciation of the scientific value of their contributions is shown by the sale of the *Transactions*, and by the frequency

with which they are translated or transcribed into the literature of other countries. But I may be permitted to point out that, in proportion as the influence of the Society has grown as an exponent of gynecological knowledge and opinion at home and abroad, so is its responsibility; and the greater the care which should be exercised on the part of the Fellows in the enunciation of opinions which, if promulgated, may possibly, though perchance unintentionally, form the groundwork for mischievous errors in practice.

I have often been struck with the curious current perversion of the views of some author who may have taken especial pains to make himself understood and to guard against misconception. In the University of London examination for degrees in Medicine, nothing was more common than to attribute to the late Sir James Simpson the practice of separating the placenta in all cases of placenta previa, when it is well known to those who have studied his papers, that he only recommended this remedy in some unusual and embarrassing conditions. But, if errors may be promulgated from mere misunderstanding, how much more mischief may arise from teachings which are themselves erroneous or pernicious! Enunciated under the auspices of this Society, and promulgated in the provinces wherever the proceedings are read, the results may be disastrous both to doctor and patient; and hence it behoves each Fellow to guard both himself and the Society against the acceptance of error, which otherwise might become as mischievous as wide-spread. Caution is more especially necessary in reference to operations which involve important issues either to the life or future health of patients; and I venture with some diffidence to delineate one or two quicksands or dangers in the present state of gynecological science.

It is, unfortunately, in the very nature of things, that exaggerated or partial views should be entertained when a new idea or a fresh method of treatment is developed; and mere enthusiasm often sways earnest men from one extreme to another. By way of illustration, I may point out that, when midwifery forceps became so perfected that in good hands they could be used in most cases with safety both to mother and child, and it became established that, as a rule, the use of instruments need not be deferred so long as heretofore—some zealous practitioners began to throw aside all precautions, to trust as little as possible to nature, and, by way of saving time, to have recourse to instrumental delivery more frequently than desirable. In like manner, one ingenious practitioner, struck by the way in which difficulty in the delivery of some head-presentations was overcome by version, actually proposed to turn in all cases of head-presentation, whenever the least delay occurred in the progress of natural labour, and the passages were sufficiently dilated.

In the department of women's diseases, there has from time to time been a tendency to give prominence to some single pathological condition, in such way as to shut out, or at least obscure, other and perhaps equally important affections of the uterus and its appendages. We have had an epoch in which the ovary was assumed to be the prime factor in all uterine ailments; we have had a period when inflammation and ulceration of the os and cervix uteri held the foremost place in uterine pathology; and now we are threatened with a reign of uterine displacements, in which the majority of symptoms of womb-displacement are attributed to flexions and versions of the organ; and, influenced no doubt by current medical opinion, patients, as they present themselves in the consulting-room, appear stricken with an epidemic of displacement, and imagine that all their discomforts are caused by dislocations of the womb, just as, at one time, the sufferers from uterine symptoms generally believed themselves to have ulceration: neither supposition, perhaps, being in accordance with the facts.

The promulgation of particular views in pathology, even if erroneous, would lead to little harm, if it did not culminate in hurtful methods of treatment, or tend to lower our *practice* in the eyes of the public and in those of our brethren who practise in other departments of our profession. But, when theories carried into practice involve proceedings which may possibly be dangerous in their immediate or remote results, or which necessitate frequent vaginal examinations, great circumspection is required in their adoption.

Imagine what would be the result if the celebrated professor who first practised division of the cervix for dysmenorrhœa and sterility were to find many imitators without his genius, who began extensively to incise the cervix in most cases of painful menstruation, or where pregnancy was desired! Or picture what would result if it were generally believed that nearly all forms of uterine disorder could only be cured by the frequent repetition of some form of cauterisation; or, again, if a large body of medical practitioners were to become possessed of the single idea that uterine displacement was the root of evil in the majority of female ailments, and that pessaries of some kind were essential to cure both married and single women so suffering!

I would beg especially not to be understood as depreciating the labours of some of those eminent pioneers who have done so much to advance our knowledge of uterine disease. It would be in the last degree unjust not to acknowledge how much we are indebted to their conscientious labours; and there is great temptation to give preponderance to subjects which have occupied so much attention, and have cost much pains in investigation. But I am anxious to guard against the acceptance of some single idea or theory, which, if ridden as a hobby, may hinder the advance of a broader and more comprehensive uterine pathology, and perchance lead to meddling and mischievous methods of treatment. The mind preoccupied with a sole idea is apt to search only within the limits of that idea, and to overlook or ignore what may be more important, but beyond and outside it. In an experimental art like ours, practice goes through phases and fashions, in accordance with prevailing principles in pathology and therapeutics; and we are not alone in this respect. The practice of physic has had its phases of bleeding, blistering, and antiphlogistics, followed by a diametrically opposite stimulating method. A mercurial plan of treatment has had its day, and has been succeeded by an antimercurial plan, and so forth.

Scientific men are sometimes charged with being so conservative, as to be unwilling to entertain our suggestions which are out of the beaten path. This seems to me a groundless charge, so far as our own profession is concerned. Its members show the greatest aptitude to receive fresh accretions to their resources, if what is new affords reasonable evidence of genuineness. The danger is, perhaps, in the opposite direction. The recent and rapid progress in the physical sciences has raised expectation too high, and has sometimes favoured a too ready acceptance of novelties, which later experience does not approve without undervaluing recent improvements.

It has seemed to me, in making a general survey of our ground, and weighing our present position, that the great impetus given of late years, by many admirable workers, to the progress of uterine surgery, has tended to throw the balance somewhat too much over to the surgical side of the scale, and that operative and mechanical methods of treatment have displaced somewhat unduly and hurtfully the medical and psychological considerations in uterine cases.

It is essential to the proper exercise of our art that, while we lend an attentive ear to every suggestion of improvement, in action we should be conservative in the truest sense of the term, particularly when interference may possibly do more harm than good. I need not recall to the initiated the dangers which beset operators in midwifery, and the reasons which induce the wise practitioner to abstain from interference except when the necessity is imperative. The current axioms about "meddlesome midwifery" are as true in our times as in former days. Experience also has abundantly proved that even minor operations on the unimpregnated uterus cannot be undertaken with the same immunity as like operations in external surgery. A simple incision, the removal of a polypus, an intrauterine injection, the insertion of an intrauterine pessary—has not infrequently been followed by grave symptoms, which, in some cases, have terminated in the death of the patient, or in the permanent maiming of the genital apparatus by peritonitis.

It is no uncommon experience for a young gynaecologist to start full of ardour for operative procedures, which, he believes, will cut short the slower and more cautious methods of cure, but ere long he discovers that even slight operations cannot be performed without hazard; and, if he have a conscientious regard for the welfare of his patients, he grows more conservative as he grows older. It is true, we have witnessed great achievements in gynaecological surgery brought about by indomitable courage and infinite pains in the face of great perils. I know no more striking illustration of this than the success which our distinguished *confère* Mr. Spencer Wells, and, following him, Dr. Thomas Keith, have attained in ovariectomy. But it must be remembered that this operation has been undertaken and perfected to avert the progress of a disease, which ere long inevitably terminated in death. The risk incurred bears a direct relation to the magnitude of the peril in which the patient stands before the operation; and there is no comparison admissible with hazardous operations which are undertaken for the alleviation of some minor ailment, or possibly for the cure of a woman who is barren, but otherwise in perfect health. While, therefore, the sagacious and prudent gynaecologist should shrink from nothing which will promote the ultimate good of his patient, he should not readily be beguiled into what is new or adventurous, without sufficient proof of its necessity, efficacy, and reasonable security, and without well considering whether some lesser measure will not bring about the same result. Further, he should be conservative of his resources, in diagnosis as well as in treatment. He who, as a rule, employs the uterine sound, without considering whether the whole circumstances are such as to afford *prima facie* evidence that it is necessary to clear up some doubt, will

certainly inflict a large amount of pain and annoyance on his patients, with a minimum of good result. The same observation applies in some degree to the use of the speculum; and, without being bound by any slavish rule on the subject, I may go so far as to say that any method of treatment for uterine affections—always supposing it to be efficient—the more readily commends itself, if it do not entail too frequent examinations *per vaginam*.

This Society, consisting as it does of so many who are eminent as obstetric teachers and practitioners, may with propriety act as moderator, when new views are propounded on matters within its province. While it gives countenance and encouragement to all sound innovations, which combine improvement with comparative safety, it may assess, so to speak, their true value and importance, and its judicial decision will command respect, in proportion to the care and caution of its deliberations.

From this aspect I regard the position of President as one of high responsibility, and I look forward with some diffidence to the exercise of the trust you have confided to me. I must, however, rely on your forbearance, and hope that, by showing a strict impartiality, I may win your approval; and, at the same time, guide the debates to a wise decision.

If the Society have already done much, there is yet ample work in store for it. Besides accumulating the valuable records of experience, there are numerous interesting subjects of inquiry which might make the reputation of Fellows who have aptitude for them. There are yet extensive mines of investigation, which have been but very partially worked, and which would well repay time expended on them. Take, for example, the diseases of the placenta. Notwithstanding what Simpson, Barnes, and others have done, much remains yet to be learnt. The whole subject of intrauterine death, comprising the pathology, causes, and prevention of abortion, and of the death of the fœtus in the later periods of pregnancy, is one full of interest, and offers a field for investigation of great extent.

Take, again, the subject of septicæmia, or blood-poisoning; how little we know as yet beyond what is conjectural; how little we know of the nature or of the origin of the poison itself, and yet how serious we know its results to be, and how helpless the wisest of us are to cope with it when extensively developed. Surely something might be done, by careful experiment and chemical analysis combined, to elucidate the subject and aid its prevention, or mitigate its effects.

One object of great practical interest on which further information is required, has been confided to a committee of able observers, nominated by the Society, to investigate and report upon. I allude to the subject of transfusion. The report is, I understand, nearly ready, and, when it is presented, it may be desirable to set apart an evening for its discussion, so that the opinions and experience of Fellows may be elicited on the general question of transfusion, and its value in actual practice.

One of your Presidents has called attention to the comparatively small number of contributions to the Society on infantile pathology. I agree in thinking this is to be regretted. The diseases of young children are commonly regarded within the province of the obstetric physician, and their treatment forms so large and important a section of work in the practice of every family doctor, that their careful and constant study becomes desirable on every available opportunity. It is well known that, from certain structures and physiological peculiarities, children are subject to diseases which differ in many important respects from those of adults. Their pathological anatomy differs remarkably from that of adult patients. If attacked by the same disease as the adult, the common ailment will, in accordance with the tender age of the patient, be modified in its course, be attended by other symptoms and complications, and perhaps terminate in a different manner. Special modes of diagnosis have to be employed in investigating children's ailments, and special therapeutics employed in their treatment.

In view of the importance of this subject, I trust that Fellows may be persuaded to bring more contributions before the Society concerning infantile pathology, and that the records may be found in next year's *Transactions*.

THE GARSTANG BOARD OF GUARDIANS have passed a resolution to petition Parliament for the repeal of the Vaccination Acts.

TESTIMONIAL.—Mr. James B. Peacock has been presented with a handsome timepiece, and a purse containing £105. On the timepiece is inscribed: "Presented to J. B. Peacock, Esq., M.R.C.S., L.R.C.P., together with a purse of gold (of the value of one hundred guineas), by his patients and friends, as a token of their esteem on the occasion of his leaving Northallerton for Darlington.—January 27th, 1875."

MATERNAL IMPRESSIONS.*

By R. J. LEE, M.D., F.R.C.P.

Assistant Physician at the Hospital for Sick Children, Great Ormond Street.

It is generally assumed that the term "maternal impressions" is intended to denote those disturbances of the minds of women which occur at a period when they are naturally more susceptible than at other times to the influence of mental trouble, or to causes which excite, depress, or in any other manner produce serious impressions on their nervous systems. The difficulty of explaining satisfactorily the manner in which the phenomena arise has induced many of our profession to regard them more often as coincidences than as the consequences, of the causes stated to have produced them; while others, who have had a larger number of examples presented to their notice, have allowed the probability of cause and effect, yet have declined to speculate on the various links which unite one with the other.

Sometimes, however, a difficulty which has long appeared insuperable is diminished when we change the point of view from which we have been accustomed to regard it, and yields to attempts to overcome it when they are made in a different method and with well organised purpose; of which we have many examples in physical science, or more familiarly in the experience of the mountaineer, who succeeds in the ascent of lofty summits by an entire change in the starting-point of approach.

Such a change of position as that to which I refer is often the result of a suggestion from those who have tried and failed to accomplish their object by one particular plan, yet have neither the time nor energy to attempt the scheme which observation leads them to believe likely to prove successful. When such persons, however, give their directions to others, it is at least necessary that they should support them by satisfactory arguments, and should place at disposal such assistance as experience enables to offer. I need hardly say that I am in the humble position of one of this class, so far as regards having failed to elucidate the causes which give rise to those departures from the ordinary course of natural development which we meet with in the fœtus and in young children, and which are referred to "mental impressions" by which the mother has been affected. There is no intention, however, on my part, to throw labour on others in which I am unwilling to share. It is really from the fact that valuable observations may be made by many members of our Society, that the following remarks and suggestions are brought under their consideration.

Instead of describing generally the various conditions which are met with in practice, and are quoted as examples of maternal impressions, we may take a case which is related by Mauriceau of an instance of the kind. The chapter in which it occurs is entitled "Of the Diseases of Women with Child," and contains excellent directions for the management of the pregnant state. (Trans. Mauriceau's work, 2nd ed., 1716, Chamberlen.)

"If she ought to govern herself well in the observation of what we have lately mentioned, she ought no less to be careful to overcome and moderate her passions as not to be excessive angry; and, above all, that she be not affrighted, nor that any melancholy news be suddenly told her; for these passions, when violent, are capable to make a woman miscarry at the moment, even at any time of her going with child; as it happened to my cousin's mother (Mrs. Dionis), a merchant dwelling in the street Quinquampo, whose father being suddenly killed with a sword by one of his servants, who, meeting him in the street, traitorously run him through out of spite and rage, because he had, some few days before, turned him out of doors. They brought immediately this ill news to his wife, then eight months gone; and presently after brought her dead husband, at which sudden fright she was immediately surprised with a great trembling, so that she was presently delivered of the said Dionis, who is to this day (which is very remarkable) troubled with a shaking in both hands, as his mother had when she was delivered of him, having yet no other inconvenience, notwithstanding he was born in the eighth month, by such an extraordinary accident; nor doth he seem to be above forty years old, though near fifty. When he signed his contract of marriage, they who knew not the reason of it, when they saw his hands shake, thought it was through fear of his bad bargain, of which they were disabused when they had heard the catastrophe that hastened his birth. Wherefore, if there be any news to tell a high-belly'd woman, let it rather be such as may moderately rejoice her (for excessive joy may likewise prejudice her in this condition): and, if there be absolute necessity to acquaint

her with bad news, let the gentlest means be contrived to do it by degrees, and not all at once.

From such cases as this, the opinion must have originated that the child *in utero* might be affected indirectly through the mother; and though, through popular ignorance, very exaggerated and doubtful statements have been made regarding the extent to which maternal impressions may affect the child, still, like most popular ideas, there are sufficient reasons, when we consider it, to justify further inquiry into the subject. We may perceive, however, that the case just related is not one of those in which the child is born with some peculiar deformity of such a nature as to produce a resemblance, fancied or otherwise, to the object which was the cause of mental disturbance to the mother. This attempt to connect the deformity or other unnatural condition in the child with the form, colour, or other peculiarity in the object, is one which is constantly being made, though a not very careful consideration of the grounds for that idea would soon lead to the conclusion that such a relationship as popularly imagined is most improbable. In the reports of cases, for example, of a child having a mark upon its face resembling a spider, or that of one born with only one leg, in consequence of the fright sustained by the mother from the sight of a spider or a cripple, we have generally evidence that the person who relates them so strongly believe, in this connection between cause and effect, that he has seen resemblances which to the sceptical mind would be quite inappreciable. For scientific purposes, it is difficult to make use of such cases, not only because the idea referred to may have led the reporter to force the resemblance to suit the theory, but because he has also probably forced the details of the occurrence of fright to the same extent and purpose.

The arguments generally urged against the theory of resemblance, if we may call it so, are of considerable force, though, indeed, of such a nature as to leave us dissatisfied, because they are negative rather than positive, and do not attempt to explain the facts by any other theory.

It has been observed that—

1. The same abnormalities occur very frequently where there has been no fright whatever.
2. In animals, as well as in the human species, corresponding deformities are met with, though there is no reason to imagine that they have been produced by fright.
3. Most deformities occur at those early periods of pregnancy when the woman is not sensible of or certain of the fact.
4. The same unnatural formation may be observed in several children of the same parent.
5. All abnormalities are rather subject to the laws of physiological development than to the effects of fright.
6. In twins, the abnormality is present in only one of the children.
7. We are aware of no direct nervous connection between the mother and child.
8. Serious physical disturbances, particularly fright, occur to pregnant women, but are not followed by abnormal conditions in the child.

Although these arguments do not explain the manner in which deformities arise, they support the theory that there is a law of variation which presides over all abnormal developments in the fœtus. It certainly would appear that they are intended to discourage the view that there is any connection between the mother and the child, and that such deformities occur in a certain proportion without any particular cause. It is probable that this view is correct, so far as regards certain forms of variation, though it would be quite reasonable to argue that the percentage theory is just as likely to be true of cause as of effect.

The fact that those deformities which are evident at once are more rare than the varieties which occur in internal organs and are only exhibited by dissection, will account for the difference in statistical returns intended to show the relative proportion between children born well and ill formed; and the general conclusion at which Forster (*Die Missbildungen des Menschen*, 1805) arrived, after an extensive inquiry into the subject, still remains true—namely, that there does not seem to be any definite numerical ratio between them. But, to decide to what extent maternal impressions are the cause of deformity—that is to say, in how many cases it is reported to have been so—we should require different statistics from those which simply exhibit the relative frequency of certain kinds of abnormality. It would be necessary, of course, to have a distinct account of the peculiar nature of the mental disturbance, the period of pregnancy at which it occurred, the duration of its effects, and, lastly, an exact anatomical account of the part or organ affected.

There are some forms of cardiac disease, of cutaneous disease, and others, in children, which you would hardly be inclined to refer to so remote a cause as the condition of the mother; and we might be disposed to allow simply that a feeble state of health in a woman is

* Read before the Medical Society of London.

sufficient to affect her child; but we might not think of connecting congenital diseases of the heart in the child with rheumatism, scarlatina, or variola, in the mother. Thus it frequently happens that examples of deficiency of the tissues of the heart, an irregular distribution or connection or deficiency of the principal blood-vessels, are reported with anatomical exactness, while no account is given of the mental or bodily condition of the parent.

There is one question the decision of which would be of great assistance; and that is, whether all deformities or deficiencies have originated very early indeed in fetal life, and have, therefore, gone on *pari passu* with the growth of other parts; or whether it is possible that some of the less serious departures from the normal condition may have had their origin at later stages of pregnancy, and that, too, where the processes of development had so far followed the ordinary laws of growth. For instance, is it possible for the septum of the ventricles, at one time perfect, to undergo such changes as to result in the formation of an opening, which, of course, assumes the actual removal of already formed tissue? Or, again, suppose the growth of a finger were arrested at the second month of pregnancy, could those conditions be produced which we meet with of absolute deficiency in consequence of absorption and the increase in surrounding parts? Can morbid processes, such as that of inflammation, affect the septum of the ventricles, and be followed by absorption and rupture? Or, in the case of a limb, may the processes of nutrition and growth be arrested and take a retrograde course?

The other view—that, from the very earliest period of existence, the course of development is arranged, and that what we term abnormalities are the preordained results of another system of growth—has undoubtedly this argument in its favour, that, in many cases of abortion, at very early periods indeed, we meet with evidence of abnormality.

Not to wander away, however, into the inescapable, let us return abruptly to the simple question, Can mental disturbances produce an influence on the *fetus in utero*? We soon begin to see that it is necessary to classify the various causes which can affect the mind. A mental impression becomes too vague a term, when the variety of emotions is considered by which the mind may be excited. Fear, hope, joy, anger, in various degrees, producing various effects, and all the other means by which the mind may be agitated or depressed, appear to be beyond the reach of classification. Some might indulge the fancy so far as to imagine that certain emotions agitate certain organs of the body in particular, and that in this way the *fetus* is affected; that, as certain emotions appear to disturb the circulation and violently agitate it, others—as, for example, long continued mental trouble—will produce disorders of nutrition by disturbing secretion and absorption.

We can understand the difficulty of establishing such a view as this; and those who are inclined to support it will probably find more assistance in the evidence of one or two careful observers, than in abstract reasoning. Without indulging in compliment, we may fairly attach considerable importance to the fact that, among such observers, Dr. Peacock has expressed an opinion in its favour. "The occurrence of accidents," he remarks, "and strong impressions upon the mind of the mother, are also supposed to conduce to the irregular development of the off-spring; and in many cases such causes appear to have operated. In several instances which have fallen under my notice, the mothers of children labouring under malformations of the heart have assigned the defects in their off-spring to strong mental impressions or shocks which they sustained during pregnancy; and there seems reason to believe that such causes, by deranging the maternal, and indirectly the fetal, circulation, might produce the effects." (*Malformations of the Heart*, p. 165-166.) We must really commence by a close examination of what we intend by an "impression", in the sense in which we use it in these cases. It is clear that the mind may be influenced through any one of the senses, more particularly through those of sight and hearing. But in daily life, it is a matter of experience that the mind is terrified, troubled, or otherwise disturbed, by causes which act directly on no particular sense, more often than by those that shock through their direct influence on sight or hearing. That part of the individual which we are in the habit of calling by the name of the feelings or the emotions, is peculiarly liable to disturbance in this way. The case that has been related is an example of emotion from ill news, a more frequent occurrence than any other to which certain abnormalities in young children may be attributed.

Fear and joy may be taken as general expressions of two classes of mental conditions, of which the latter rarely, as far as is known, produces those effects we are considering.

Fear may arise in a variety of ways, and may affect the moral nature very differently, according to the manner and duration of its action. It is difficult to say what we mean by fright, as distinct from fear. Fear, or again anxiety, which would appear to be a protracted species

of fear, is decidedly capable of producing impressions on the mind of a woman, and of being followed by abnormalities in her child. We have a class of cases where actual danger has been threatened, and a different state of excitement has been produced from that which follows sudden and alarming intelligence. Thus, we have instances of women whose lives have been threatened by another person; or where the life of one of their own children or of another person has been in danger from fire or violence in their presence; where they have been alarmed by an accident or a thunderstorm, whether injured or not by it. In these cases, we perceive that the senses are more or less directly affected, but decidedly in a manner different from that in which either sudden intelligence, or any object of disgust or fear, produces an impression. It would appear, therefore, that a "maternal impression" is not quite so easy to define as might be imagined. We can only admit that, through the feelings and through the senses, a variety of impressions may be made, varying principally with the extent to which moral and animal feelings are separately or simultaneously excited.

It is unnecessary for me to assure you that, instead of the subject appearing more intelligible on reflection and careful observation, it grows in difficulty, and seems more and more inexplicable. To increase this difficulty, it is found that a maternal impression may affect, not the bodily, but the intellectual, condition of a child, producing results practically far more serious than peculiar local abnormalities, such as deficiency of fingers, toes, etc.

I have yet one remark to make concerning the anatomical arrangement of abnormalities, which I ought to have introduced before. By this method, the deformities are classified according to the separate organs and parts in which they occur; for instance, those of the skull and spinal canal are grouped together; those of the hands and feet form another class, and so on; as well for internal as external parts. The number of names which such a system requires must necessarily be very considerable, since all parts of the body of a *fetus* are liable to abnormal growth; and, although there may appear to be certain laws which govern these abnormalities—that is to say, that certain forms are more frequent or more rare than others—yet we are not assisted by such a method in the explanation of the causes which may have produced them. Nor, indeed, does it seem to me that we are much enlightened by the terms used in the classification—terms necessarily abnormal and monstrous; such, for example, as *terata anakatadidyma*, a class of double monsters united above and below, and containing as species *prosopo-thorakopagus*, *thorakopagus*, *rachipagus*.

It is clear that it is necessary to classify, if possible, the various causes which may produce an impression; but, as I have already remarked, such an attempt would be impossible in our present state of knowledge of the connection between external objects and the sensorium. It would be necessary for us to be able to explain how impressions produce effects in healthy persons before we could hope to discover their influence in pregnancy: for example, such cases as that of uterine hemorrhage in a woman who has almost recovered from parturition, in consequence of the fright occasioned by seeing one of her children in flames, or of the sudden arrest of the secretion of milk in a similar condition from a somewhat similar cause.

Nor does the argument, that there is no direct nervous connection between the mother and child *in utero*, appear to be of much value, when we have instances of young children being affected with convulsions during suckling, in consequence of the mother having been alarmed by sudden fright or ill news. These are facts well established by experience, though they do not admit of direct anatomical explanation.

It would, on reflection, appear to be most natural that maternal impressions should be more frequently followed by some unnatural condition of the intellect of the child than by abnormalities of growth, and this point is worthy of particular attention.

It is at least a more reasonable view, and decidedly more practical, than that which attempts to connect the malformation with the object of terror. When the cause of fright has been of a moral character, and has principally excited the feelings, we should expect the results to be exhibited in an abnormality of the intellect rather than of the growth. To confirm our expectation, we find by experience that it is true. The instances of mental abnormality have been numerous which have come under my notice. Such cases of imbecility or deficiency of intellect in the child are almost always attributed by the mother to mental disturbance previous to its birth, while this is by no means so frequently the case in malformation. The ratio, too, between the numbers of cases of marked malformation and those of intellectual abnormality is much greater than you could suppose, and I do not think we should be exaggerating in estimating it as nine to one.

The term intellectual abnormality may very reasonably be objected to, and it would be quite fair to demand a definition of it. If a defini-

tion would assist in the explanation of the cause why a child should suffer in this way, we might be anxious to obtain it; but we can easily afford to leave the definition for the present, and inquire into the phenomena or the simple symptoms and conditions of these children. At an early age, that is, before two years are completed, it is premature to judge of the intellect of a child; yet there are symptoms which enable one to predict that, with the progress of time, there will not be a corresponding progress in its intellectual development. The important functions performed by the organs of speech, and the evidence of comprehension which we usually expect to be exhibited by the expression and the obedience of a child, are more or less deficient. Sometimes the sense of hearing and the powers of speech are simultaneously affected; in other cases, the appreciation of sound and harmony is above the average, while speech and intelligence, by which I mean a knowledge of the use of things and the influence of example, are absent.

When first these cases came under my observation, it appeared to me to be a more interesting question to determine what anatomical condition could have produced this deficiency in speech than to decide the exact nature of the maternal impression to which it was attributed.

More extensive experience, however, has induced me for the present to confine my observation to the particular effects of purely emotional disturbances during pregnancy upon the child. We lose sight of such cases after the age of six or seven, because the parents have by that time discovered that there is little hope from medical treatment, and, therefore, seek for safe asylums for the children. Without entering into the details of the earliest symptoms of intellectual deficiency arising from maternal impression on this occasion, I still beg to express the hope that at another time I may be permitted to bring a series of cases before you; while, after the attention of the members of this Society has been directed to the investigation in daily practice of the view I have attempted to establish, it is more than probable that some important conclusions may result from a comparison of our opinions upon it.

MATERNAL IMPRESSIONS.*

By JAMES CLAPPERTON, L.R.C.P. Edin., Market Deeping.

THE subject which I have the honour to bring before the notice of the members of this Association to-day is one not only of singular interest in itself, but is specially adapted for discussion by family practitioners. However much metropolitan men may have the advantage of the general bulk of country practitioners in many matters, our position secures for us a claim to be heard on the subject of those peculiar modifications of development in the fetus which depend upon some fright, or other strong impression, made upon the nervous system of the mother, during the early months of pregnancy. Most of us who are engaged in midwifery practice have become more or less familiar with "the mother's mark" commonly met with in the form of discolourations of the integument, and pilous naevi; we are all well acquainted with the "strawberry", "raspberry", or "the mouse", which is so frequently seen. At times, the resemblance to some natural object is very marked; so faithful to nature, indeed, that the "mark" is recognisable by the most cursory glance, so close the simulation of the original object. At other times, a deeper impression is made upon the nerve-centres of the mother, and a distinct modification of the form of the fetus is the result. This would seem often, indeed commonly, to be due to arrest of development, the primitive embryo retaining in its arrested evolution the characteristics of the creature which has occasioned the fright. There is something weirdly interesting in the fact that, when the object of fright is, as it frequently is, a living creature, one of the lower animals, its own configuration should be impressed upon the plastic form of the hapless being undergoing its evolution within the body of the startled or terrified mother.

In a case related by Mr. C. M. Thompson (of Sevenoaks) in the *BRITISH MEDICAL JOURNAL* of April 4th, the object of fright was a toad; and, when the child was born, the attendant, who had naturally been much puzzled with the presentation, found that the child's head and face exactly resembled a toad. From my own experience, I can quite understand how puzzled he might be. Though not a very old practitioner, I have met with four cases, which I shall briefly relate.

CASE I.—Mrs. H., aged 30, a healthy woman, went to the flour-bin; and, when she put her hand into the bin, a mouse ran across her arm. The child was born with a mark on its arm, which now distinctly resembles a mouse.

CASE II.—Mrs. G., aged 25, when pregnant with her third child, went into the straw-yard for some straw; a rat jumped out, and in her fright she put her hand across her throat. The child was born with a mark across the throat, which now resembles a rat in shape and colour. In her next pregnancy, she was frightened by a dog, and placed her hand over the sacrum. The child was born with a mark over the sacrum, which now resembles a dog. I may add, that the idea of selecting the place for the mark, which they deem inevitable, by striking the hand upon some part which is not likely to be seen, is prevalent amongst country people.

CASE III.—Mrs. T., aged 34, who had had several children, was returning from market, when a toad jumped across her path and frightened her; she went on to the full period, feeling as in her other pregnancies, except the dread of something being wrong. I was sent for to attend her, and, on my arrival, found her delivered of a still-born child free from "marks". She was suffering from strong labour-pains. On passing the finger into the os, no presentation could be detected. I introduced my hand, and with difficulty brought down a foot; after a few pains, the poor woman was delivered of a child resembling a toad, which died in a few moments.

CASE IV.—Mrs. H., aged 23, when about three months gone in her second pregnancy, was startled by one of the neighbours running into her house, and saying her pigs were fighting in the yard. She ran out and endeavoured to separate them, but without effect. From then until the sixth month, she was always thinking about the pigs, and expressed to her friends that she feared her child would be disfigured. On rupturing the membranes, a very large quantity of water came away; shortly afterwards, a female child made its descent. Then this specimen which I have the honour to lay before you was born.

Dr. Blundell, in his work on *Midwifery*, page 1012, relates an unusual case which occurred in the practice of Dr. Lee, where the monster was brainless, and was accounted for by the patient in the following manner. During her pregnancy, prompted by curiosity, she watched the doctor while he was engaged in examining the head of her son, who had died of hydrocephalus, and she saw the operation at the moment when the calvarium and brain were removed. A list of scores of interesting cases might be made, if care were only taken to put them on record, by the different medical men scattered through the country, who are interested in this matter; and I shall be most grateful to those gentlemen who shall from time to time publish such cases, or, if they do not choose to do that, if they will only address a private communication to me on the subject. Of course it is needless to say, that I should keep perfect faith with any gentleman who should desire to have his name kept out of the description of the cases he may furnish to me, in subsequent publication of the collected cases. I have received a communication from Dr. R. J. Lee, as to the effects of general fright or emotion upon the development of the fetal viscera, especially of the heart and brain, which opens up a most interesting field of research. Its further discussion must, however, form the subject of some future paper.

There are two points of interest in these curious cases: one a speculative one, and one a very practical one. We will take the speculatively interesting matter first. How do these modifications of development on the part of the child follow the fright given to the mother? By what means is the change brought about? There is no doubt that the starting-point is a "state of expectant attention", to use the language of Carpenter, upon the part of the mother. It is the direction of consciousness to the part, the fixing the attention upon it, either by voluntary action on the part of the mother, who broods over the matter, and so prints the impression on the growing plastic tissues of her child; or by involuntary fixation of attention, by some action of the lower and deeper seated cerebral centres, independently of, and unconnected with, the higher volitional centres. Such persistent attention, voluntary or involuntary, affects the embryo in the womb. How is this influence of nervous impressions upon the organic functions brought about? The most careful examination of the umbilical cord has failed to discover, in the mass of the cord, the sarcode or jelly-like material of which it is composed, any trace of nerve-fibres. Carpenter is of opinion that this effect must be produced upon the maternal blood, and transmitted through it to the fetus, since there is no nervous communication between the parent and the offspring (*Principles of Human Physiology*, sec. 733). Dalton, in his work on *Physiology*, page 629, is of opinion that it is through the placental circulation that those disturbing effects are produced upon the nutrition of the fetus, and the mode in which these effects may be produced is readily understood from what has been said of the anatomy and functions of the placenta. But, with all due deference to such authorities, I may venture to suggest that there may possibly be such a nerve-communication existing in an altogether unexplored direction; I mean in the vaso-motor nerves which

* Read before the Obstetric Medicine Section at the Annual Meeting of the Medical British Association in Norwich, August 1874.

belong to every artery, and probably to the arteries of the cord. It is quite true that the fetal tufts dip into the placental sinuses, and, as it were, float freely in the tiny wells of maternal blood. But, nevertheless, there may exist some nerve-communication in the structures which hold these fetal tufts down in the placental sinuses. The possibility of such nerve-communication is suggested by the transmission of impressions from the mother's brain to the fetal tissues. We are all aware that such mental impressions have produced very curious results under different circumstances; for instance, the well known case where a mother saw her son's fingers crushed by a falling window, and in half an hour's time her own finger showed changes similar to those in her boy's hand—changes which could only be the result of nervous influence. It would further appear that, whatever be the means of communication, the transmission is much more easily effected in some systems than in others. We know that, in numerous cases, intense anxiety on the part of the mother, a persistent fear that some change in her child will correspond with something that she has seen that has shocked her, has not resulted in any effect. On the other hand, these transmitted effects are occasionally recurrent in the same individual, as stated in the second case I related, and in Mr. Thompson's case, where such change occurred a second time in the same woman. In my case, the first was a rat, the second a dog; in Mr. Thompson's, the first was a toad, and the second a tortoise, which left their impress upon the embryo. The systems of these women must have been inordinately susceptible to such impressions. This arrest of development, producing a resemblance to some natural object, some lower form of the vertebrata, is rendered comprehensible by the speculations and observations of Von Baer. Long before the hypothesis of Mr. Darwin had stirred the still waters of our ideas as to progressive development, Von Baer had observed that the human embryo corresponded, at different periods of its existence, to the fetal forms of the vertebrata. At first, the human ovum is undistinguishable from that of a fish, as in the well known ovum of the late Professor Agassiz. It was a vertebrate ovum, and no more could be said. Then it is homologous to that of a reptile, then to that of a bird, and ultimately to that of a mammal.

Such shocks, then, might arrest the development of the embryo, when they occur (as they did in the cases I have related) before quickening. In fact, in all the cases I am acquainted with, the impression was received in the early months of pregnancy. This being the case, it produces such a perversion of tissue-growth as induces a retrograde movement in the fetal lineaments, already assuming the characteristics of humanity, and a reversion to a lower type. Certain it is that these impressions occur some time before quickening, and that a certain amount of development secures the fetus from the effects of any of these modifying causes. Neither are such impressions made upon the nerve-centres of the mother, and communicated to the fetal form, confined to the human mother only. Certainly we have no record of a shock affecting any lower animal when frightened during pregnancy; but a very interesting case is given by Daniell in his *Indol Sports*, which bears upon this matter. Daniell had a pointer bitch of pure breed, which he was conveying to a pure sire residing at some distance. We all know how carefully the true sportsman guards against the possibility of any *faint pas* which might militate against the purity of the strain. Consequently, when Daniell, in passing through a village, found the susceptible dogs pressing their attention upon his convoy, and the flirtation with one objectionable cur threatening to become specially serious, he felt no hesitation in shooting the intrusive canine cavalier. No physical intercourse had ever taken place, and the object of his journey was carefully secured. But, to his dismay, all the pups bore the impress of the cur he had sacrificed, and the nerve-centres of the pointer-bitch transmitted to her progeny the image which was indelibly stamped on them and fixed in her memory.

The transmission of these impressions is a matter which deserves more attention than it attracts, and a larger collection of cases and further investigation of the subject may perhaps elucidate the question, and clear up some of its difficulties. But it is now time to leave this section of the subject, and turn our attention to the practically interesting side of the question. This is the relation of such malformations to the diagnosis of the presentation. I can assure you, from my own experience, that the diagnosis of such a malformation, when it forms the presenting portion of the fetus, is a very puzzling matter. No writer on obstetrics with whom I am acquainted has ever described such malformations as we are now considering in relation to their presentation, and the difficulties arising therefrom. Even that brilliantly suggestive man, my obstetrical teacher Sir J. Simpson, did not give us any indications for the recognition of such modified forms; neither, so far as I am aware, have any statistics been collected to show that unusual presentations are more than ordinarily frequent in fetuses so altered, or to demonstrate that such changes in the configuration of the fetal

head, altering its relation to the pubic cavity, modify the position of the fetus, or cause unnatural presentations to be more frequent. Such modified and altered fetuses, when the change is pronounced, never survive. It is fortunate that they do not, as it renders it quite unnecessary to consider the question from the moral side, of the propriety or necessity of inducing their destruction by acts either of commission or omission. Still it is somewhat suggestive that babies so altered, anencephalous or other monsters, always seem conscious of the impropriety of survival in their case, and atone for their shortcomings and indiscretions by early demise. Probably they are not equal to maintaining an individual and separate existence.

CASE OF FRACTURE THROUGH BOTH RAMI OF THE LOWER JAW, TREATED BY EXTERNAL INCISION AND THE WIRE SUTURE.

By THOMAS ANNANDALE, F.R.S.E.,

Surgeon to the Edinburgh Infirmary, and Lecturer on Clinical Surgery.

IN September last, I was asked to meet Dr. Moodie of Stirling in consultation on the case of J. C., aged 18, who had received a severe injury to his face from a railway waggon. A few days previously to my visit, the patient, when following his employment of a clerk on the railway, was knocked down, and the wheel of a waggon passed over the lower part of his face. Great swelling of the whole face followed the injury; and Dr. Moodie, who was called to see him, at once recognised a fracture through both rami of the jaw. Careful means were used to keep the fragments in position, but without success, and I was accordingly asked to see the patient.

An examination determined a fracture on the right side of the lower jaw at the junction of the angle and ramus, and one on the left side through the ramus, immediately above the angle. The body of the bone was uninjured. By a little manipulation and elevation of the body of the bone, the fragments could be brought nearly together; but, when the force was removed, the fragments at once separated, and the body of the jaw fell downwards so as to leave the mouth open and fixed in this position, as the patient had no control over the movements of the bone. There was a small wound on the right side of the cheek anterior to the seat of fracture, which was discharging pus freely. The experience of the treatment which had already been adopted having shown that some special means would be required to keep the fragments together, it was decided that the patient should be brought to town and placed under my care in the infirmary. Accordingly, he was admitted into my wards on September 28th; and, on the following day, I placed him under the influence of chloroform, and proceeded to secure the fragments together by means of the wire suture. Owing to the position of the fractures, it was found impossible to drill the jaw from the inside of the mouth, and I therefore made an external incision about two inches in length over the seat of fracture on the right side, exposed the fragments, and having drilled them, brought them together with strong silver wire. A similar incision was made over the fracture on the left side, and the fragments were drilled and treated as on the right side. The fragments on this side could not be brought accurately together, but they were secured as nearly so as possible. After the operation, there was still a slight tendency for the body of the jaw to become depressed, and in order to counteract this, a piece of soft gutta-percha was introduced between the molars of the upper and lower jaws on the left side, and held in this situation until it took a mould of the parts and became hard. It was then allowed to remain in this position, and a chin-bandage was applied to keep the jaws steady. The suppuration, which had existed before the operation, continued for several weeks, and from time to time small portions of necrosed bone separated, and were removed by the mouth. On November 13th, the wire on the left side being quite loose, was removed; and, on December 5th, that on the right side also became loose, and was removed. Both wires had been twisted on the inner aspect of the jaw at the time of the operation, and consequently both were removed by the mouth. After the removal of the second wire, the suppuration almost ceased, and the patient was dismissed on Dec. 9th. On January 6th, he returned to show himself, and there was then only a small superficial wound on the right side. The movements of the jaw were excellent, and the patient could masticate with ease. When the jaws were closed together, there was a slight lateral displacement of the lower one; but with this exception, and a slight swelling of one cheek, the parts were natural in appearance.

REMARKS.—Fractures of the lower jaw have been occasionally treated by means of the wire suture (see Hamilton on *Fractures and Dislocations*, fourth edition, p. 119), and I have myself used this method

in several cases of comminuted fracture of the body of the bone, drilling the bone through the mouth or through a wound which already existed. Mr. Bickersteth of Liverpool (*Medico-Chirurgical Transactions*, vol. xlvii) has suggested and practised a method of securing the fractured ends of this and other bones by means of a drill, and has given a most interesting account of several cases in which it was successfully adopted. The employment of special external incisions, as in the case related, has rarely if ever been practised in connection with recent fractures of the lower jaw. The objection to them is the resulting external cicatrix or cicatrices which, although not of so much consequence in the male, as the whiskers will usually completely cover them, must cause some deformity in the female. For this reason, I would only advocate an external incision or incisions in cases which cannot be successfully treated by other means. In the removal of the tongue, or portions of it, and in some cases of tumour of the jaw, I always now bring the ends of the divided jaw together by means of the wire suture; and my experience of this method is, that it is safe, efficient, and easy of application. Since writing this, Mr. Mason of St. Thomas's Hospital has been kind enough to direct my attention to the ingenious method of employing the wire suture in bringing the end of bones together, practised by him (*Medico-Chirurgical Transactions*, vol. liv). His method allows the wire to be easily removed at any time, and is, therefore, to be preferred to that which has usually been employed, should the case admit of the needle being passed in an oblique direction through both ends of the bone.

ANOTHER CASE OF POISONING BY HOMŒOPATHIC SOLUTION OF CAMPHOR.

By GEORGE JOHNSON, M.D., F.R.S.,
Physician to King's College Hospital.

In a paper of mine published in the last volume of the *Clinical Society's Transactions*, there will be found notes of five cases in which symptoms more or less distressing and alarming were caused by homœopathic concentrated solution of camphor. I am indebted for the particulars of the following case to a former pupil, who gives me permission to publish them, but begs me to withhold his name, for the reason that it is a rule of the public service in which he is engaged that no medical officer shall publish his cases without special permission, which is not always granted when asked for. I give the case as reported in a letter addressed to me by the medical officer who saw the patient.

"I was called in to see a lady about thirty-five years of age, and found her with a very pale face and weak pulse. She said she had been suffering from a bad cold and feverishness; that she had got up late, and had her dinner at about two o'clock. About an hour after dinner, her sister, who is an experienced nurse, dropped seven drops of homœopathic solution of camphor on a lump of sugar, and gave it to her. Immediately after taking it, she was attacked with a very faint feeling, which compelled her to lie down flat on the hearth-rug; and she nearly lost consciousness. This lasted about five minutes. When I arrived, her face was very pale, and her pulse was weak. I ordered her to bed, and gave her some aromatic spirit of ammonia and lavender. She was very drowsy after she got to bed, but had no more vertigo or faintness; and in a day or two she got rid of her cold. I am led to believe that this was a case of camphor-poisoning similar to those which you have published, for the following reasons: the attack occurred immediately after taking a dose of camphor; the patient says that she had never before had a similar feeling of faintness; and the vertigo or faint was followed by drowsiness."

There can, I think, be no doubt that the symptoms were a direct result of the camphor. The dose was smaller than in any other case which I have met with in which poisoning has resulted from the incautious use of this dangerous compound. The homœopathic concentrated solution of camphor is a saturated solution of camphor in alcohol, the proportion being an ounce of camphor to an ounce and a quarter of spirit. Seven drops would be an uncertain quantity; but seven measured minims would contain rather more than five and a half grains of camphor. In one of the cases which I have recorded in the *Transactions* of the Clinical Society (vol. vii), a dose of twenty-five drops, taken by a young lady for a cold, caused violent convulsions and nervous sequelæ which continued for several months. In another case, eight doses of three drops each, taken by a clergyman within forty minutes, caused violent headache, sickness, and inability to work for two months. In a case communicated to the *BRITISH MEDICAL JOURNAL* by Dr. Clifford Allbutt (Dec. 6th, 1873), two doses of at the most ten drops each rendered a robust mountain-guide so giddy that he was unable to proceed on his journey, and he had to be deposited in a

cave for safety. Lastly, in two other cases, a teaspoonful dose caused convulsions and coma.

It is time that the public should be warned of the danger which they incur by the use of this poisonous homœopathic concentrated solution of camphor, which is more than seven times the strength of ordinary spirit of camphor. It is notorious that the modern disciples of Hahnemann have gone from the ludicrous extreme of infinitesimal dilution to the dangerous extreme of the greatest possible concentration of active and poisonous drugs.

ON THE RELATIONS BETWEEN DIPHTHERIA AND SCARLET FEVER.*

By ARTHUR RANSOME, M.A., M.D. Cantab.,
Lecturer on Public Health in Owens College, Manchester.

THE following case shows the close connection between these two diseases.

On February 23rd last year, a boy at school had scarlet fever. He was isolated until March 25th, when his brother saw him and took the complaint. Other cases occurred at the school on the 29th, 30th, and 31st. On April 2nd, one of the masters had a rigor and sore-throat; he left at once, and was seen by me next day. On the third day, diphtheritic patches covered the tonsils; but there was no rash. Slight albuminuria accompanied the pyrexia; both disappeared by the seventh day. On April 9th, six days after he arrived at home, his mother was attacked, membranous exudation appearing in both tonsils; but there was no albuminuria, and no rash.

The origin of these cases must surely be traced to the epidemic of scarlet fever at the school; for there were no cases of diphtheria either in the neighbourhood of the school or near their home. The close relationship of these diseases has often been pointed out. In the *Report of the Medical Officer to the Privy Council for 1859*, Dr. Burdon Sanderson gives cases of diphtheria and scarlet fever coexisting; there also I find three cases of diphtheria following three of scarlet fever, and the former spreading to a neighbouring cottage. These diseases have much in common. They are alike in their zymotic or epidemic character; both are characterised by high pyrexia; their chief point of attack is the throat and the glands of the neck; and a rash is found in both diseases. Their sequelæ also are similar: suppuration in the lymphatic glands, ulceration of the ears, arthritic affections with or without cardiac complication, kidney-disease and dropsy, general or localised paralysis of the nervous system. I have seen each and all of these consequences after both diseases.

Some physicians have been led by these points of resemblance to regard them as one disease, the same poison producing different manifestations; but, in spite of their similarity, I venture to think the differences are too important and too numerous to permit so simple a solution of the problem. In the first place, diphtheria is seen to arise directly from scarlet fever. I have never known the converse action. There are other etiological differences. Though both are contagious, diphtheria is less so, and more frequently occurs in single cases. Where several cases occur together, some general cause is probably concerned. Scarlet fever is more frequently conveyed by clothes or other fomites, by attendants on the sick, and it may be conveyed by means of milk. I am not aware that diphtheria has ever spread by any of these means. The two diseases differ in their geographical distribution. Diphtheria is common in India, where scarlet fever is unknown. Colonies and all new settlements seem peculiarly liable to diphtheria; it has appeared in the Australian colonies and in South America, attacking the otherwise healthy town of Buenos Ayres. In Lima, it was noticed that the black races withstand its contagion. It selects high and well drained districts, when low-lying lands in the vicinity escape. Dr. Blake, in the *Transactions of the Medical Society of California*, mentions a most fatal epidemic at an elevation of 4,000 feet. Many places in England subject to diphtheria are either high or well drained. Scarlet fever also haunts certain places; but these scarlet-fever fields are not at high levels, nor are they those in which diphtheria is especially prevalent. Diphtheria is often connected with defects in the house-drainage, not always due to imperfection in the house-connection with a general sewage-system, but to leakage from private cesspools; so that a question of spontaneous origin may arise in this disease, which is hardly admissible with respect to scarlet fever. Season has a different influence on the two diseases: scarlet fever being most prevalent in the autumn, low barometric pressure and greater humidity in the air favouring its diffusion; while diphtheria may arise at any season, and, in my own experience, its most virulent epidemics have occurred in the summer months.

* Abstract of a paper read before the Epidemiological Society of London, January 13th, 1875.

Another difference is found in the fact that scarlet fever is not often associated with other diseases, while diphtheritic affections are not uncommon in the course of other pyrexial disorders. It is recorded in the Report of the Diphtheria Subcommittee of the Epidemiological Society, that, in the epidemic of 1861, this disease occurred fifty-seven times alone, thirty-four times in association with scarlatina, nine times with small-pox, seven with measles, six with fever, and three times each with ordinary sore-throat, croup, and catarrh. But in the nature and symptoms of the two diseases are points of likeness too great to allow us to rank them as varieties of the same species. Thus, the rash of diphtheria is often absent, is very variable as to the time of its appearance; it occurs seldom at the outset of the malady, and I have seen it as late as the third week of its course. The period at which albuminuria sets in is also different, often appearing in severe cases of diphtheria within the first two or three days, whilst in scarlatina it seldom sets in until degeneration of the kidney is commencing. There is, indeed, an entire absence of definiteness about the duration of the symptoms of diphtheria, which of itself marks it off from the regular sequence of events in scarlet fever. I have known it last for six weeks, and even two months, without any evident affection of the cervical glands, but with constant formation of exudation on the fauces or on other mucous surfaces.

The mode in which diphtheria localises itself on the mucous membranes, or on the broken surfaces of the skin, would probably be sufficient to separate it from any other disease. I do not know that scarlet fever ever attacks the larynx; but I have seen the diphtheritic membrane appear in different cases upon wounds of the skin, upon blistered surfaces, and upon nearly all the mucous membranes of the body—the lips, cheeks, nose, ears, pharynx, larynx, trachea, and bronchi, and on the anus and vulva; and different epidemics have differed strangely in this respect; in one, the throat would always be the point selected for attack; and in another, the other mucous membranes. It is somewhat remarkable in the latter case that, although the disease was mild and there were no deaths, the subsequent complications were much more frequent and troublesome.

The last point of difference that I shall mention is the fact that, while scarlet fever seldom reappears again in the same individual, diphtheria seems by its first attack to confer no immunity from subsequent seizures; on the contrary, the susceptibility of the throat seems to be rather increased.

Upon taking a survey of all these relations existing between scarlet fever and diphtheria, it is evident that they are distinct diseases, and yet that there is some very close and definite connection between them. Wherein the bond consists, it is not easy to point out. From the manner in which the diphtheritic poison seeks out the highest points of the best-drained localities, it has appeared to me most probable that the virus of this disease must be of a more rarefied and subtle nature than the germs that produce scarlet fever.

It is possible that the nature of some other ferments may throw some light upon this subject. I would specially call attention to the discovery by M. Berthelot (*Comptes Rendus*, vol. I, p. 980) of an unorganised glucosic ferment in an infusion of yeast resembling diastase; also to the fact that one fermentation by organised beings frequently prepares the way for another. It may be suggested, that in one of these ways the singular relations existing between scarlatina and diphtheria might be accounted for. I do not venture to affirm that there is a strict analogy between these fermentative actions and the zymosis of scarlatina and diphtheria; but, as there exist in nature ferments requiring the presence of living germs, and others acting independently of them, so there are disease ferments with organic germs reproducing themselves, and others which have no definite term of life, and which are not self-reproductive.

It is probable that, in most cases of fermentation, the living being connected with each kind of this action is of a specific nature, and peculiar to the medium or to the food upon which it lives. In some instances, a ferment either during or at the end of its operation will produce the conditions favourable to the growth of another kind of germ, as seen in the crowd of vibrios appearing at the end of a mycoid fermentation; so the pyrexial state may produce the condition most congenial to the diphtheritic ferment, whether that may prove to be an organised germ or an unorganised catalytic ferment. As my excuse for offering these suggestions, I will quote, in conclusion, the words of the great English philosopher Robert Boyle. "He that thoroughly understands the nature of ferments and fermentation shall probably be much better able than he that ignores them to give a fair account of several diseases (as well fevers as others) which will perhaps be never thoroughly understood without an insight into the doctrine of fermentation." (*Works*, ed. 1744, vol. i, p. 476.)

MALARIA.

By T. INMAN, M.D. Lond.,

Late Lecturer on Medicine at the Liverpool Royal Infirmary School of Medicine; Consulting Physician of the Liverpool Royal Infirmary.

As I anticipate that my friend Dr. Oldham will, in due time, make his remarks upon what has appeared on this subject in the *JOURNAL*, I do not intend farther to prolong the controversy, especially as I find it difficult to do so without being satirical upon the logic of those who have supported the old idea of malaria.

For example, to my mind it appears strange that an ague-fit coming on after a gravel-walk has been raked, or a pit dug, must necessarily rise from a disturbance of the earth. I can recall plenty of cases in which ditches full of vegetable *dbris*, stagnant ponds, and soil of all sorts, have been dug out and dug over. In one, this process was marked by an attack of sciatica in the master; in another, by gout; in another, by chicken-pox; in another, by pneumonia; in another, by a drunken bout; in another, by catarrh; in another, by paralysis; in another, by chorea; and in another, by gonorrhœa. Would not every one "write me down an ass" if I associated any one of these complaints with an upturning of sods, delving ditches, taking up potatoes, storing carrots, turnips, or mangold, or with other farm-labour? Then, if an attack of ague should come on, are we to be asked to jump to the conclusion that the complaint was caused by raking a gravel-walk, or digging a grave in the nearest cemetery? Again, all the correspondents have avoided the very important point, that emanations, whether from marsh or river, trench or pit, are the most abundant and incessant during the heat of the day, a period when nobody pretends—except in such cases when the body is suddenly chilled by a hailstorm, or by wading through cold rivers, or by a cold wind from the mountains, or simply by a drying zephyr when the body is covered with thin garments soaked with perspiration, rain, etc.—that agues are caught. The well known Maremma and Pontine Marshes and the Campagna around Rome are innocuous during the day, when the sun is hot and every emanation strong.

When night falls, and emanation ceases, then comes the danger of ague, etc. Clearly, then, the cause must be sought in a something which there is in common between nights in general and those conditions that will give ague during the day. This something, most unquestionably, is not malaria, or an emanation from any soil.

I commend the inquiry to those whose experience is commensurate with their acumen. I am quite aware how easy it is to try to put down a thinker by an array of so-called facts; and I have known a "stay-at-home" astronomer convict of inaccurate observations the whole of the officers of an exploring expedition, who insisted that their chronometers went wrong for three days, under the influence of a land-breeze from Australia. The head man was not so silly as to stick up for the malarious effect of proximity to land, but re-examined his calculations, and discovered the error.

Some of the writers in the *JOURNAL* seem wholly to have misunderstood the bad effect of sleeping on the deck of a ship being dependent upon (1) hard work and exhaustion under a hot sun; (2) sleeping where the body is certain to be chilled by radiation or a cold land-wind; and they make merry over the fact that many are taken ill between decks. Unquestionably they are, when all the air-holes are kept open, and admit a chilly land-breeze. Men on board ships in the deadliest African rivers escape fevers—as far as they are caught on ship-board—by closing the windows at sundown. At sea, the air in the tropics is equable day and night, when not chilled by a cold land-breeze. In like manner, one may cross the Pontine Marshes by night, by excluding from the carriage in which one rides the bitter cold; not that which we call bitter in England, but very severe to those accustomed to a day temperature of 140 degs. in the sun and 88 to 92 degs. in the shade, and who are too lightly clad to bear a sudden fall to 60 or 50 degs. during the hours of darkness. No amount of experience in the field can alter the physical fact that in many places in hot climates the nights are colder than the days, especially when the sky is clear. Even frost occurs occasionally by night on the Sahara; and the Arab always keeps his most valued horses under cover after sundown, and in good stables too.

Nor can any amount of experience, from the Indus to the Pole, convince us that very formidable diseases—e.g., pneumonia and bronchitis—are not frequently produced by a severe chill after fatigue and exposure to heat. I should pay no compliment to the writers if I were to count *seriatim* all those complaints—even including purulent periostitis and necrosis—which have fairly been traced to violent chill after exposure to heat, without a microscope being able to detect in the air or water

to which the sufferers were exposed either fungoid spores or marsh malaria.

Once more I would add, that I have had the privilege of conversing familiarly with medical and other residents of Sierra Leone, Cape Coast Castle, Rangoon, Birmah, Fernando Po, the Gold Coast, the aguish districts of South America and the United States, the worst part of the West Indies, the fen districts of Cambridgeshire, and the worst parts of Italy. Some of my informants have had ague repeatedly; others have seen every one around them, including negroes, down with fever (I do not refer, of course, to yellow or other contagious fever), whilst they have escaped wholly during a residence of five years on the same spot.

The experience thus obtained is not to be despised, even although I have no personal knowledge of other malarious districts than those of Cambridgeshire and Italy.

THOUGHTS ON THE MANAGEMENT OF INCURABLE CHRONIC HEART-DISEASE.

By C. M. DURRANT, M.D., F.R.C.P.,
Physician to the East Suffolk and Ipswich Hospital.

I HAVE been induced to jot down a few passing reflections on the subject of this paper, from the circumstance that, while the treatment by drugs has undergone an almost exhaustive investigation by writers on heart-disease, its general management by moral and hygienic suggestions has been proportionately overlooked, and its paramount importance scarcely recognised.

The first question, then, that occurs to me—and a very important one it is—Do we, as practitioners, sufficiently inform our patient suffering from the consequences of an incurably diseased heart of the nature of his malady, with a view to his adopting such measures in the conduct of himself as may tend to ward off a suddenly fatal termination? The result of the daily inquiries that are held will, I think, give a negative answer to this question.

A man uses sudden, and perhaps violent, exertion; falls; dies; an inquest is held. His usual medical attendant states that he has known (for some years possibly) that the individual has been the subject of an organic disease of the heart, and a verdict of death from natural causes is returned. The question arises, Had the patient been made aware of the precise nature of his complaint, and of its fatally hazardous character under the influence of sudden exertion? Too frequently, I believe, the individual undertakes the hurried movements which result in death in entire ignorance of his precarious condition; whereas, had he understood it, he might possibly, by his own prudence and care, have postponed the fatal termination. I am sure that we must all have been familiar with cases of sudden death from heart-disease, in which the patient, from a kind, but mistaken, feeling on the part both of physician and friends, has been left in absolute ignorance of his danger, or with only a vague conviction of something being wrong, yet without the remotest idea of what he should himself do to prevent a suddenly fatal catastrophe. The fear lest the shock, on being informed of his dangerous condition, produce the very result that we wish to avoid is, I believe, an altogether mistaken one. I am satisfied that no one with heart-disease will die one moment sooner for having been properly made aware of its existence; and I feel that we are all in duty bound, as honest responsible practitioners, and as Christians, to adopt the golden rule of doing as we should wish, under like circumstances, to be done by. If the patient be gently and kindly told by his medical attendant that, although his heart is seriously affected, still, if he carry out implicitly in his own person the rules laid down for his guidance, he may hope with confidence to have his life prolonged, I do not believe that anything but good can accrue from adopting this course. I am convinced that these suggestions have hitherto been very culpably neglected or insufficiently enforced, and that, if they were generally adopted, many cases of heart-disease now terminating with such painful suddenness might have life prolonged, and thus afford to the patient and to his family a lengthened interchange of social happiness. If, then, we admit the propriety of enlightening our patient as to his condition of danger, we have next to consider the especial influences which he will be called upon, for his own safety, to resist.

The first that will present itself to our minds will be the careful avoidance of sudden and hurried motion. Nothing is so likely to cause sudden death in advanced heart-disease as this. Hurrying to catch a train, attempting to walk rapidly up hill, especially in the face of a strong wind; dragging or lifting weights, and many other movements which will occur to the medical attendant to interdict, must be sedulously avoided by the patient. In cases of regurgitant aortic disease and great thinning of the ventricular walls, as well as in fatty de-

generation of their structure, this injunction will be doubly necessary. I believe that prolonged travelling by train may be highly prejudicial, and tend to a fatal termination by exhausting nerve-force. I have seen two cases of sudden death follow upon a railway journey, which I could only explain in this way. Both were subjects of advanced valvular disease.

Another very necessary precaution, and one not to be neglected by the patient without the greatest hazard, is the avoidance of partaking at any one time of a large distending meal, even though the food taken be of an easily assimilable character. This is a fruitful, but not a sufficiently recognised, cause of sudden death in heart-disease. This senile syncope, as it has been called, may be generally traced to the filling the enfeebled stomach beyond its power of disposing of its contents. Undigested food, acting as a foreign body, irritates the stomachal nerves; and, thus irritation being reflected upon the cardiac nerves, they in their turn fail to influence sufficiently the coronary vessels, and hence the cardiac syncope, and, if not relieved, fatal termination. In all cases of organic heart-disease, the meals, let it be remembered, should be small in quantity, of easy assimilation, and of frequent repetition; so that the heart may not be pressed upon by a distended stomach, on the one hand, or its due supply of nerve-force exhausted by prolonged abstinence, on the other.

Cold liquids, if taken in excess, and especially if quickly followed by exercise, and more particularly if this exercise be up an ascent, are very likely, by exciting nerve-irritation, to produce cardiac syncope and sudden death. In these days of almost universal tea-drinking, and at all hours, it requires some courage to inveigh against the popular custom; neither is it my intention to do so, beyond a few observations bearing upon the especial subject under our consideration. I think that the discrepancy in the minds of medical men in regard to the effects of tea, and the diametrically opposed opinions which are so freely enunciated, are much to be deprecated. Tea acts chiefly as a nerve-stimulant, and, when taken in moderation as to quantity, and not too strong, it can in no wise be injurious in heart-disease. When taken under these circumstances, it exhilarates and restores, and may often well supply the place of alcohol, with its subsequently depressing and intoxicating effects. With some persons, it should be remarked, tea will be found to act as a powerful nerve-irritant, amounting almost to a poison, and producing cardiac feebleness, flatulence, irregularity of the heart's action, and the many nervous disturbances which we must all have witnessed, even if we have not in our own persons experienced its discomforts. In such idiosyncracies, the use of tea and coffee must be strictly prohibited.

Another question arises, as to how far a patient labouring under serious heart-disease should debar himself from sexual intercourse. I believe, as a rule, that it should be absolutely forbidden, especially in the more serious conditions of heart above referred to.

A very troublesome symptom, difficult to combat, and attended with extreme hazard, is the great restlessness of some patients, the subjects of advanced valvular disease. If the patient have been in the habit of frequent travelling when well, we shall find the greatest difficulty in keeping him at home. Now, sudden death away from his own family circle, as I have more than once seen, is by no means unlikely to occur. The disturbed circulation, affecting the brain, and producing great irritability, renders these cases peculiarly trying and difficult to manage. Firmness, kindness, and the most truthful admission of the real condition of the sufferer, while the attendant dangers are distinctly set before him, will alone avail to influence him, and to keep him at home.

Passive carriage-motion is good; but, as a rule, it will be better, I believe, to debar the patient from horse-exercise. Early hours must be enjoined; and, if the patient be wakeful at night, nourishment in the shape of beef-tea with brandy must be taken, and especially in the early morning, when the nerve-force is at its lowest ebb. Milk, with rum or brandy, may also be taken shortly before rising. In all cases of advanced heart-disease, the patient, as a rule, should invariably carry a small flask of brandy in his pocket.

In reference to medicinal treatment, it is not my intention to dilate further than to state that, in mitral valve-disease, aperients freely given, with a view to unload the venous capillaries, will afford the most relief. In aortic regurgitation, I have often seen much advantage derived from the infusion of senega, with hyaline and spirit of nitrous ether, as recommended by the late Dr. Barlow.

In senile syncope, the result of an over-distended stomach, no time must be lost in emptying this organ by an emetic, to be followed as quickly as circumstances will admit by the administration of full doses of brandy with hot water. In those cases of advanced heart disease in which dropsy is superadded, and in which diuretics often signally fail, temporary relief may sometimes be obtained from full doses of quinine.

SURGICAL MEMORANDA.

THE POLAPUS KNIFE-HOOK.

IT IS a testimony to the value of the instrument described by Dr. Lawson Parryes in the JOURNAL of the 23rd instant, since I was, I believe, the first to employ it. I am, I think, right in saying that the idea was suggested to Dr. Parryes in conversation with Dr. Frank of Baltimore, and Dr. Whittell of San Francisco, the former of whom spoke of a knife-hook he had invented for dividing the muscle in strabismus. However that may be, the first instrument made was by Messrs. Weiss for Dr. Whittell, who brought it to me on January 11th, at the Central London Throat and Ear Hospital. Three cases of aural polyp presented themselves, on two of which I operated with the knife-hook, and the third was similarly treated by Dr. Whittell. In all the success was complete. One case was that of a child aged thirteen, who, having been severely frightened when seven years old, had been since subject to epileptic fits, and was certainly the most timorous patient I have ever encountered. The merest touch, or even the sight of the forceps or snare, caused such alarm, that I quite despaired of ever being able to operate. The knife is, however, such a benign-looking instrument, that the child permitted it to be used with scarcely an objection. With aural, as with nasal or laryngeal polyp, it is impossible to say what is the best instrument for general use, because it is very difficult to accurately gauge beforehand the seated extent of surface of attachment of the growth; but I have no doubt that the knife-hook will prove a most useful addition to—and probably a substitute for—some of the many ingenious, but more complicated polypus-extractors, already in use.

LINCOLN BROWNE, F.R.C.S. (Edn.), Surgeon and Aural Surgeon to the Royal Society of Musicians.

CLINICAL MEMORANDA.

THE PATHOLOGY AND TREATMENT OF CHOLERA.

AFTER reading Dr. Crombie's paper in the JOURNAL of Jan. 9th, I referred to B. Cuthwaite's *Review* for 1848. I freely admit that Dr. Bell has forestalled me generally in what I have written on the pathology of cholera collapse, although there are some points on which I differ from him, but which would take up too much space to enter into here. I was aware that Dr. Bell considered cholera a form of malarious fever; but I did not know his views about the pathology of the disease. I can only say that, when I mentioned my opinions to some medical friends of standing and long experience in India, in 1869, I was assured that my views were original. Some even thought them too original. For the last two years I have only seen the *Indian Medical Gazette* occasionally; and I have not observed the remarks referred to by Dr. Crombie. But now, with regard to the point of real practical importance—the treatment: Dr. Bell recommends bleeding in collapse. The treatment has been discussed so freely by various writers, that I will only say that I think it probable bleeding would do good in many cases if the blood could be obtained from the veins, which is the difficulty. The drugs that Dr. Bell suggests are, *opium with iron*. Now if, as Dr. Bell wrote, and as I perfectly agree with him, the nervous system in cholera collapse is in an abnormally high state of tone, what is the use of giving nerve-tonics? The remedies that seem to me more appropriate are the true sedatives which tend to lower this tonic condition and relax spasm. I hope that the hypodermic injection of chloral hydrate will not yet be condemned, but that it may have an extended trial, taking care to have the drug *very pure and fresh*, and that the point of the syringe be thrust into the muscles, as suggested by Mr. Higginson, the civil surgeon of Kheri, in Oude, whose experience of this mode of treatment is certainly very encouraging. But I beg to recommend other sedatives as well. In the paper that appeared in the *Indian Annals of Medical Science* for March, 1870, I suggested that hydropyrene acid should be administered subcutaneously. One minim, dissolved in twenty minims of water, might be injected and repeated at intervals, or the patient might inhale the fumes of the acid from a bottle; this, I fancy, would speedily produce an eruct, but I have had no opportunity of using it. Aconite, veratrum viride, and other sedatives might also be tried; and I trust that medical officers in India will carefully try these various remedies, and record the results of their experience in the treatment of cholera collapse by sedatives.

A. R. HALL, Surgeon Army Medical Department, Topsham.

OBSTETRIC MEMORANDA.

IS PUERPERAL FEVER CONTAGIOUS?

IN the JOURNAL of January 16th, is recorded the committal of a midwife for trial on a charge of manslaughter by conveying puerperal fever to patients; and the important question is asked, "Is it certain that puerperal fever is contagious?" Most practitioners, I imagine, would answer unhesitatingly in the affirmative. As bearing on this question, the following cases have occurred in my practice during the last few weeks.—CASE I. December 23rd, 1874. Mrs. A., had her first labour: the presentation was natural, and the labour fairly easy; peritonitis set in on the fifth day, and death occurred on January 2nd, 1875. The lacteal secretion was scanty from the first; the lochia were satisfactory to the last. Previously to this, I had not had a case of peritonitis for several years. CASE II. December 28th, 1874. Mrs. B. was confined; the presentation was natural, and the labour easy. She recovered without a bad symptom. CASE III. January 3rd, 1875. I delivered Mrs. C. The presentation was natural; the labour easy. Recovery took place without a bad symptom. CASE IV. January 5th, 1875. Mrs. D. was delivered. The presentation was footling, the labour tedious, requiring more manual assistance than usual. She recovered without a bad symptom. CASE V. January 5th, 1875. Mrs. E. was confined for the first time. The presentation was natural, the labour fairly easy. Peritonitis set in on the fifth day; and she died on January 13th. In this, as in the first case, the lacteal secretion was scanty, but the lochia satisfactory throughout. CASE VI. On January 14th, 1875, I was requested to attend Mrs. F., which I declined to do, and advised that another practitioner should take charge of the case. Calling next day to inquire after the patient (as I had attended all her family for many years), I found that, instead of having other medical assistance, she had been delivered by her mother, who had not only assisted to nurse the last case, but had actually helped to wash and lay out the corpse. Recovery took place without a bad symptom. I offer no remarks on the foregoing cases; I simply submit them to the consideration and comments of my brother practitioners.

JOHN A. ORR, A.B., F.R.C.S. (Edn.), *Edinburgh*

(*Brit. Med. Journal*)

THERAPEUTIC MEMORANDA.

JABORANDI.

ON January 29th, I had the pleasure of bringing a detailed account of this interesting and important drug, and of some experiments I had made for the purpose of observing its action, before the Pathological and Clinical Section of the Birmingham Branch of the Association. Thanks to the courtesy of Messrs. Southall, who kindly sent me some specimens of jaborandi about two months ago, I have had an early opportunity of testing the physiological effects of this new and remarkable medicine. I am able fully to confirm the statements which have been made by Dr. Ringer and others concerning the power of jaborandi to produce very copious sweating and salivation. For the following account of the results of a dose of the drug, given to a healthy lad, aged 17, I am indebted to Dr. Bisset Smith, one of the house-pharmacians at the Queen's Hospital. On January 5th, at 10.30 A.M., John W. drank an infusion prepared from six *grammes* (one drachm and a half) of jaborandi. Just before taking the drug, his skin was dry, his temperature in the axilla was 98.25 deg. Fahr.; pulse, 90. At 11.10 A.M., the temperature was 97.9 deg. Fahr.; pulse, 104. The skin was moist over the whole of the body; the face and forehead were perspiring profusely. At this time, the lad complained that his mouth was filling with water. He said there was a mist before his eyes. At 11.40 A.M., the temperature was 97.9 deg. Fahr.; pulse, 96. The skin was perspiring profusely. Salivation continued. He said he could not see anything on the other side of the ward, a distance of about twenty-five feet; he could see anyone standing by the side of his bed perfectly distinctly. The pupils were not altered from their normal condition. At 12.10 P.M., the temperature was 96.6 deg. Fahr.; pulse, 90. The skin was less moist. There was no derangement of vision; no salivation. At 1 P.M., the skin was of natural moisture; temperature, 96.8 deg. Fahr.; pulse, 96. I was very much struck by the derangement of vision produced in this case, for I had not seen such a condition recorded as one of the results of the administration of the drug. Mr. Martindale has since described the effects of a dose of jaborandi upon his own vision; and Mr. Tweedy has published the results of a series of elaborate investigations, which he has conducted with the view of esta-

blishing the exact effect of the medicine upon the eye. In the case I have just quoted, the effect of jaborandi upon the bodily temperature was most marked. The temperature began to fall as the sweating became evident. In one hour and forty minutes after taking the infusion, the lad's temperature had fallen from 98.2 deg. Fahr. to 96.6 deg.

JAMES SAWYER, M.D., M.R.C.P.,
Physician to the Queen's Hospital, Birmingham.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JANUARY 26TH, 1875.

C. J. B. WILLIAMS, M.D., F.R.S., President, in the Chair.

ON THE TEMPERATURE OF PHTHISIS PULMONALIS AND ON THE VARIOUS CONDITIONS INFLUENCING IT.

BY C. THEODORE WILLIAMS, M.A., M.D., F.R.C.P.

THE author, after briefly reviewing the labours of Jochmann, Lebert, Küchenmeister, Ringer, Wilson Fox, and others on the thermometry of phthisis, proceeded to demonstrate the reasons why hitherto no definite laws governing the rises and falls of the temperature in the disease had been discovered; the main point being the comparatively few observations taken *per diem*, and the acute and exceptional character of the cases under observation. A clinical and pathological account was then given of one hundred and four consumptive patients, inmates of the Brompton Hospital, and, therefore, subjected to the same equable atmospheric and hygienic conditions, in all of whom the temperature was taken at least five times, and in many of them seven, ten, and twelve times daily, for periods varying from seven to thirty days. The patients were sixty-three males and forty-one females, embracing all acute and chronic forms of the disease except acute tuberculosis. The temperatures were taken for the most part in the axilla, and in some instances, for comparison, in the mouth, by the clinical assistants and by Dr. WILLIAMS himself, with thermometers manufactured by the best makers. These observations amounted in number to between four thousand and five thousand. To ascertain more fully the exact thermometrical phenomena of the disease, and especially the night changes, in twelve cases an hourly record was carried out for twenty-four consecutive hours, and in some instances it was repeated for a second similar period. The state of the pulse, respiration, skin, bowels, and urine was likewise noted; as also the time of meals and the amount of food taken. The cases are classified in the following manner, according to stages: 1. First stage, active (where formation of tubercle was taking place); 2. First stage, quiescent; 3. Second stage, that of softening; 4. Third stage, active (with increasing excavation and tuberculation); 5. Third stage, quiescent (or chronic cavity). The results of the analyses under these headings were then given, and the temperature at each of the hours of observation, viz., 8, 10, and 11 A.M., 2, 5, 8, 10, 11, and 12 P.M., as also the intermediate day temperatures occasionally taken and the night observations. The media, maxima, and minima of each stage were stated, and tables and charts were exhibited to explain more fully the method of calculation and the results arrived at. The influence of the states of consolidation and of tubercle formation, of softening and of excavation, as well as extension of disease, on the temperature, were dwelt upon, and illustrative instances of each given; the pathological state being proved in many cases by *post mortem* examinations. The chief conclusions as to the diurnal temperature of the disease were as follows. In a large number of chronic phthisis cases, the temperature is normal or subnormal, sometimes falling to between 93 deg. and 94 deg. Fahr.; a continuity of low temperatures being most marked in the first and third quiescent classes. In pyrexial cases, the temperature is seldom very high, 104.6 deg. Fahr. being the highest recorded. In the majority, a marked rise takes place after 2 P.M., and a rapid fall occurs after 10 P.M., which continues throughout the night, until its minimum, sometimes as low as 94 deg. is reached before 7 A.M.; a slight recovery is then perceptible, the normal being seldom, however, attained before 9 or 10 o'clock. This temperature wave may be shifted a few hours, the rise taking place later in the afternoon, the high temperature being maintained farther on into the night, and the lowering consequently delayed by some hours. Any continuous rise of temperature is followed by a certain amount of collapse, though not always to a corresponding degree. The disease in all its stages shows the post meridian rise and the nocturnal fall, with the early morning collapse temperatures; and that the latter is a characteristic of phthisis is proved by Dr. Williams' observations on a healthy man (placed under similar conditions to the consumptive patients), in whom the night temperatures did not fall materially below the day

ones. The first stage exhibits a more gradual rise and fewer extremes of temperature than the third. In the third stage, the temperatures are the highest and the lowest; both afternoon pyrexia and nocturnal collapse being most strongly marked, the one having been known to rise to 104 deg. Fahr., the other to sink to 93 deg. Fahr., thus exhibiting a range of 11 degrees. The second stage shows intermediate thermal features between the first and third stages, active. Tubercle may form, and the various processes of lung-disorganisation may proceed uninterruptedly without apparently causing any considerable rise of temperature, and may even be accompanied by a subnormal temperature; this being probably due to the collapse influence on the constitution. Many of the variations in the phenomena are to be explained by the formation of pus, the liquefaction of adjoining tissues, the imprisonment of the purulent and caseous compounds, and their subsequent evacuation by expectoration. Phthisis has a distinct temperature course, marked, on account of these changes, by great intermissions; but the idea that in each case it depends on individual idiosyncrasy is founded on imperfect observation. In all cases, two principal agencies appear to determine the temperature course: first, an excessive action of the natural processes by which the body heat is maintained; secondly, the influence of collapse, proceeding from the well marked weakening of the constitutional powers in phthisis. These two agencies are continually struggling for the mastery, and the result of this conflict is the temperature course of the disease. The influence of the first is seen in the rise in the afternoon and evening well marked in the active forms of all three stages, and regularly recurring day after day for long periods; the influence of the second was shown in the rapid nocturnal fall and low temperatures of early morning; the collapse influence was also seen in the subnormal day temperatures, occasionally occurring in all stages of the disease, and even where the active processes of lung tuberculation, of softening, and of excavation may be taking place. It is, however, chiefly noted in the quiescent forms of the first and third stages. When low temperatures accompany active forms of the disease, it is probable that the collapse influence is stronger than the pyrexial, and, therefore, masks it. When the chart shows occasional fitful variations, these agencies are, perhaps, evenly balanced, and may alternately prevail, as is witnessed in the end temperatures of consumption; and to these derivations, noticed in advanced cases, may be ascribed the prevailing, but erroneous opinion of phthisis having no definite temperature courses. The author concluded with a careful comparison of weights of the above patients, with their temperatures, and made some deductions therefrom.

Dr. WILSON FOX said that the profession must be much indebted to anyone who would take such trouble in the recording of temperatures as Dr. Williams had done. For some years, he had attempted the same thing; but he had not yet made an analysis of the results. The fact as to the morning and evening temperatures was generally known. What was wanted was, to know at what hours the temperature could be taken with the greatest accuracy. It appeared that the highest evening temperature was at 5 P.M.; but there seemed to be this difficulty, that on no two days at the same hour was the temperature alike. For instance, the temperature at 8 A.M.—the lowest—might be in successive days 97 deg., 98 deg., 99 deg., and 100 deg.; and, at 2 or 3 P.M., it might be 101 deg., 102 deg., or 103 deg. These facts must influence our ideas as to treatment; they must show that the use of therapeutic agents (excepting the cold bath) must be guided by the vitality of the patient rather than by the thermometer. Phthisis was one of the exhausting diseases; chronic suppuration was another. In a case of chronic suppuration following delivery, the extreme variation of temperature was 10 deg. He believed that Dr. Burdon Sanderson regarded great variations in temperature as indicative of suppurative fever. He thought that it was not the existence of pus, but the process of its formation, that led to pyrexia. The more inflammatory processes tending to destruction took place, the more frequent were the variations of temperature. There was, however, an exception to this in pneumonia. It was not yet possible to give the reasons for the variations in individual cases; but Dr. Fox believed that at some future day this would become possible.—Dr. DOUGLAS POWELL objected to Dr. Williams' view of the unity of phthisis in all its forms. He thought that a more useful classification could have been made than that into stages. Taking the first and second stages together, anyone who had studied the subject carefully, as Dr. Williams had done, must be struck with the different ways in which the disease commenced. When cases of all kinds were mixed, the mean results obtained were less valuable than they would be if a classification were made. The observations of Dr. Williams as to evening temperatures were of much value; the great fact, however, which had come out, was the great fall of temperature in the early morning hours; and this would probably be of much importance in treatment. This fall must be due, he thought, to exhaustion; it might,

perhaps, be avoided by feeding the patient at night. He asked whether Dr. Williams had made any observations as to the effect of food in modifying the fall of temperature. It had been suggested that the best plan of preventing night-sweats was to feed the patients. The most striking facts were those observed in the third stage; it was towards the end of the disease that the physical signs merged into one kind.—Dr. DRYSDALE had observed, in the North London Hospital for Consumption at Hampstead, that, for a month or two at a time, almost every patient increased in weight, no matter what their temperature might be. He agreed very much with Dr. Williams in his objections to Niemeyer's doctrine of the varieties of phthisis. The only variety that he sometimes met with was one which he attributed to syphilis. He thought that, in miliary tuberculosis, the temperature would be high in proportion to the number of tubercles.—Dr. T. H. GREEN asked whether the pyrexia in the third stage was due to disintegration and softening, or to the presence of the first stage of the disease in some other part of the lung. He believed that the latter was the cause. He asked also whether the thermometer would indicate the occurrence of an infective process in phthisis.—Mr. HERBERT PAGE said that the curves of temperature in the first stage of phthisis resembled what was seen in surgical cases, where the occurrence of suppuration was marked by similar variations.—Dr. LEARD asked whether the observations on temperature would assist in the diagnosis of the stages of phthisis.—Dr. SYMES THOMPSON said that previous observers found that phthisical patients presented idiosyncrasies which rendered thermometric observations futile as regarded treatment. He thought that it had been proved that quinine was a powerful agent in keeping down a high elevation of temperature; but how far real good was done by preventing a rise of temperature, was another question.—Dr. CURNOW had taken the temperatures of several of Dr. Thompson's patients in the Brompton Hospital by day and by night. There was great difficulty in finding the averages, although the temperatures touched at certain parts of the day. In some cases complicated with diabetes, there was no rise of temperature. With regard to the influence of the formation of pus, similar fluctuations of temperature were observed in cases of softening of the brain after embolism. Hence, the formation of pus did not sufficiently explain the variations of temperature. The same was the case in separation of fibrin in the blood, leading to metastatic abscesses.—Dr. THEODORE WILLIAMS thanked the Society for the careful criticism which his paper had received, and for the suggestions given, which he would not fail to lay to heart in his future work. In reply to the various speakers, he stated that, though it was true that it had been known that morning temperatures were lower than evening in consumption, the exact temperature course, with its variations, was now depicted for the first time, with its remarkable afternoon rise, and still more striking nocturnal fall. As to irregularity of temperatures taken at the same hour, this was not more the case in phthisis than in health, where the observations varied considerably; but variations of this kind in phthisis were sometimes to be explained by a shifting of the whole temperature course by an hour or so. He was strongly of opinion that the chart of the third stage (active class) was typical of suppuration; and various speakers had strengthened this conclusion by adducing evidence from other suppurative diseases, medical and surgical. The low temperature of the early morning was due to exhaustion, and might possibly be avoided by feeding the patient through the night; but his observations on this point were not yet complete. Whether the local infective process in the lung from a caseous centre could be detected by temperature, he could not tell; but, in several instances where general infection of the system had taken place, it had been characterised by a chart resembling that of pyæmia. He was aware of his classification being rather too simple; but, the results of investigations on this point having been confirmatory of the unity of phthisis, he preferred a few distinct classes, with well marked features, to a number of small divisions hardly to be distinguished from each other. The thermometer might sometimes detect the formation of tubercle before physical signs did; but, on the other hand, tubercle might form without any rise or fall of temperature. The best hours for clinical records in phthisis were: for the low temperatures, from 3 to 6 A.M.; for the high, from 5 to 8 P.M. Dr. Theodore Williams felt much indebted to the Secretary for his admirable reading of a paper, which, abounding as it did in statistics, was difficult to render very palatable.

EPIDEMIOLOGICAL SOCIETY OF LONDON.

WEDNESDAY, JANUARY 13th, 1875.

W. R. E. SMART, M.D., C.B., Inspector-General R.N., President, in the Chair.

The Relations between Diphtheria and Scarlet Fever.—By ARTHUR RANSOME, M.A., M.D. [The paper is printed in abstract at p. 172.]—Dr. SQUIRE fully concurred with Dr. Ransome in considering diph-

theria and scarlet fever as specifically distinct; he had known diphtheria arise from scarlet fever, but had never seen diphtheria give rise to scarlet fever. Dr. Ransome had ably set forth the pathological distinctions: his observations on the disputed question of rash confirmed observations made by Fothergill and by the Spanish writers of an earlier time. The period for the occurrence of albuminuria in the two diseases marked an important difference. Agreeing with much in this paper, it might be permitted him to doubt if the etiological differences were quite as great as they were there assumed to be. He had known four deaths from diphtheria at an elevation of 1,000 feet, in North Wales; but, would not the infection of scarlet fever spread among the susceptible of any Alpine village, whatever the elevation, when conveyed thither, just as plague had done in years gone by? In diphtheria, it was important to disinfect cloths and handkerchiefs used by the sick, to guard against the conveyance of the disease by *fomites*; both it and scarlet fever might be disseminated by sewer-gas, and water might be the means of conveyance. The geographical differences were not quite ascertained. An old friend and fellow-student, the late Dr. Chucker-butty, had satisfied himself of the identity of scarlatina in Calcutta and in London. Hot climates and seasons diminished some of the risks of scarlatina, without affecting the fatality of diphtheria. Scarlatina was not completely self-protective; some persons repeatedly had scarlatina sore-throats; and there were instances of a protective effect resulting from diphtheria. The persistence of the morbid process to six or eight weeks in diphtheria closely corresponded to what was often observed in scarlet fever; nor were the sequelæ altogether indefinite. We knew when, and in what order, to expect paralytic complications. Both diseases were frequently spread by convalescents six or eight weeks from their commencement, and in both an early separation of the healthy from the sick gives them security; if either disease had been contracted, it would show itself quickly, with this specific difference, that scarlet fever was seldom delayed beyond the third or fifth day, while diphtheria was not unfrequently eight days latent.—Dr. MURRAY remarked that scarlet fever in India was seldom severe, while diphtheria was often fatal. Dengue differed from scarlet fever, among other points, in this, that it caused no mortality.—Mr. LAWSON spoke as to the existence of both diphtheria and scarlet fever at the Cape. A caution was necessary in receiving the first accounts of any diseases in the colonies or abroad as proofs of their first appearance; they were often first reported only when attention had been drawn to them by their attracting notice at home.—Dr. SMART described the distinctive features of dengue; the suddenness of the attack and intensity of the feeling of illness contrasting strongly with the rapid convalescence in most cases; it certainly was not scarlet fever, and many of the Europeans seized with it must have previously had scarlet fever. He had never met with scarlet fever in hot climates. The dark races were not exempt from diphtheria; in the epidemic in the West Indies, which he had described in the *Transactions* of the Society, some of the most characteristic cases were among the blacks. Buenos Ayres had long ceased to merit its original designation; though well situated, and, doubtless, with good air once, yet, with increase of population and neglect of drainage, the sandy soil, on a bank of clay saturated with sewage, became the home of cholera, of fever, and, no doubt, of diphtheria also.

MEDICAL SOCIETY OF LONDON.

MONDAY, JANUARY 11th, 1875.

VICTOR DE MÉRIC, F.R.C.S., President, in the Chair.

Malignant Tumour of the Leg: Amputation.—Mr. HENRY SMITH related the particulars of a case of malignant tumour of the leg requiring amputation. The patient was a gentleman, aged 51, intensely gouty. Six months before Mr. Smith saw him, he had noticed a small swelling at the middle third of the front of the leg, which, though painless, slowly increased. A country practitioner saw it, and punctured it twice, when nothing but a little blood was evacuated. When seen by Mr. Smith, it was a soft somewhat flattened swelling, about the size of a medlar, situated over the front of the tibia just at the junction of the upper with the middle third; it was adherent to the skin. He at once pronounced it to be malignant, and recommended that an attempt should be made to remove it, and, if necessary, that amputation should be performed. Another surgeon who was consulted advised the same course, but recommended amputation through the knee-joint, to give the patient a better chance of non-recurrence. Mr. Smith amputated through the knee, sawing off the condyles. The patient did well. On examination, the tumour was found to be of a medullary kind, involving the bone extensively on its surface, and extending deeply down, but for a very limited space, into the medullary membrane. There were several inches of healthy bone between this point and the knee. Mr. Smith

desired to obtain the opinion of the Fellows whether the better plan would have been to amputate through the continuity of healthy bone, or through the joint. Sir William Fergusson was assured, from his own large experience, that it was neither justifiable nor necessary to amputate beyond the bone when there was plenty of healthy tissue to cut through. Sir James Paget and others, on the contrary, held the opinion that there was much more chance of a recurrence of the disease if the bone involved were not entirely removed. This was a very serious point to settle, as amputation of the thigh in a man beyond the prime of life was fatal in 25 or 30 per cent. of the cases, whereas, in amputation below the knee, the mortality was reduced to at least one-half of this. With regard to the liability of recurrence of the disease being greater or less after each operation, there was, as far as he knew, no reliable information.—The PRESIDENT said that, if he were to be operated on himself, he would choose the greater operation, though the rate of mortality was higher in it, rather than the more serious danger of the disease not being eradicated by an insufficient operation.—Mr. MAUNDER remarked that his principle in these operations was, the tumour being local and the constitution not infected, to cut widely round the tumour, so as to insure its total removal. In a similar case to that of Mr. Smith, he cut through the knee-joint with the happiest results. The patient had an excellent stump, and there had been no return of the disease for three years.—Mr. BRYANT regretted that Mr. Smith had not given the vertical section of the bone, as then the exact extent of the disease could have been ascertained. He did not think it necessary in all cases to remove the whole of one organ when attacked with malignant disease; for, when the lower third of the tibia was diseased, it was not necessary to amputate at the knee-joint. He highly approved of Mr. Smith's operation at the knee in this case; but criticised his division of the condyles, as this at once produced section of the bone, and exposed the patient to the danger of pyæmia.—Mr. GANT cited several cases of similar operation which did well.—Mr. ROYES BELL gave an instance of a child similarly operated on, which recovered in a week.

The Least Sacrifice of Parts as a Principle of Surgical Practice.—Mr. BRYANT read a paper on the least sacrifice of parts, which, he maintained, ought to be a leading principle of surgical practice. He explained the principle as one that forbade the surgeon to sacrifice more of the body than the absolute necessities of the case demanded; that called upon him to remove the disease, but no more; that enabled him in accidental surgery to make a flap for an amputation wherever he could, and in some cases to make no flap at all, but to leave the case to nature to repair; and, in pathological surgery, to cut through tissues infiltrated with inflammatory deposits rather than go above a joint or take away more of a limb than the necessities of the case demanded. He condensed the subject into three main propositions, each of which he illustrated by cases. The first proposition was: "That, in case of division or accident, no more of the body is to be taken away than the necessities of the case demand." He illustrated this chiefly from the surgery of the foot. At first sight, the proposition might appear to be a truism; but he asked if it were not true that, in cases of disease of the metatarsal bones or joints, surgeons were not too apt to regard the individual case as a good one for Chopart's operation, or Pirogoff's, or Syme's, and to forget that a good recovery of the foot might ensue on removal of the diseased bone or bones without any amputation at all. In support of this, he quoted Mr. Lister (Holmes's *System of Surgery*, second edition, vol. v), who expressed his opinion "that Syme's amputation is calculated to supersede entirely that of Chopart's, besides taking the place of amputation of the leg in the majority of cases formerly supposed to demand it." He entirely dissented from these views; he believed that, for local disease alone, no form of amputation of the foot should be entertained until less severe measures had been employed and failed; that, when amputation of the foot was called for, the minimum amount of foot should be taken away; that, when a Chopart's operation would suffice, a Pirogoff's should not be thought of; that, when a Pirogoff's was applicable, a Syme's should not be entertained; and that an amputation of the whole foot was never to be undertaken when the disease could be removed by less severe measures. The remarks made were as applicable to other parts as to the foot. Fingers and thumbs were often removed in cases of injury that, if left to nature, might often be saved. Joints were excised that might be saved by free incisions, or by the removal of necrosed bone; and amputations were performed above a joint or high up a limb in order that good flaps might be made. He illustrated all these points by cases, quoting seven cases of disease of the different tarsal bones, cured by the removal of the diseased bone; and three of extensive disease treated respectively by Chopart's and Syme's amputations, or by amputation of the leg. In disease of the bones of the foot, he had met with a case in which the resection of a tarsal bone was called for; for bone that was not dead was reparable, and to take this

away was too often to take away that which, if left, would make good the parts that had died. The author then proceeded to illustrate the value of the proposition by the treatment of cases of diseased joint, and dwelt for some time upon the value of free incisions into suppurating joints. He referred to thirteen cases successfully treated by this method; and stated his belief that a free cut into a disorganised articulation was rarely followed by any other than a good result; that, when the suppurative process was due to synovial disease, a recovery without further surgical interference might be looked for; when it was due to local necrosis, the incision helped nature towards recovery by expediting exfoliation and the subsequent removal of the bone by either natural processes or some surgical proceeding. In more severe cases, the incisions gave relief, and in no way added to the mischief. The treatment of disease of the joints due to local necrosis was then considered, and a series of ten cases was read, including examples of disease of the shoulder, elbow, hip, knee, and ankle joints, in which recovery followed the removal of dead bone from the articulations. The second proposition was: "That, to carry out this principle, the surgeon may, in pathological amputations, fearlessly divide tissues infiltrated with organised inflammatory products, and even cut through the walls of suppurating cavities or through diseased joints, more particularly to save amputating above a joint." Mr. Bryant illustrated this proposition by the particulars of ten cases, in all of which recovery took place. The third proposition was: "That, in accidental surgery, parts irreparably injured are alone to be removed, and no healthy tissues are to be sacrificed in order to perform a recognised, and probably a named, operation; that, to these ends, the surgeon ought to utilise even doubtfully useful integument, or even leave a stump to granulate, when, by so doing, some portion of the shaft of a bone can be left, a joint saved, or amputation above a joint avoided." In the surgery of the hand, this practice was strongly advised, more particularly the injuries of the thumb. Amputation of a thumb, unless smashed irreparably, the author condemned; and, under all circumstances, the irreparably injured parts ought alone to be taken away, and doubtfully viable skin left. Cases were quoted to illustrate the proposition: ten of the toes; one of the foot; a Chopart's amputation, in which a long anterior flap was made; one of crushed arm, which was left to nature to granulate, and a good stump left; two of crushed legs, in which a rapid recovery followed amputation at the knee-joint; and one of ruptured popliteal artery, treated in the same way with success. The author concluded by stating that he could still further illustrate the value of the principle "of the least sacrifice of parts", pointing out how Sir W. Fergusson had always urged the removal of tumours of the jaw from within, and Sir J. Paget tumours of bone generally by enucleation.—The PRESIDENT said that attempting to save parts often failed. He would like to know what dressings were used.—Mr. ADAMS remarked that the author's cases involved the great principles of conservative surgery. He briefly reviewed the fall of amputation and the rise of conservative surgery under the hands of Brodie, Syme, Ferguson, and others. Excision was first advocated; but now it appeared that Mr. Bryant advocated simple incision into the joint, and he believed Mr. Gay was the first to carry out this practice.—Mr. H. SMITH said that Mr. Bryant's views were by no means new. He had learnt the practice of incising joints that were suppurating many years ago from Mr. Gay. It was a mode of proceeding which he highly approved.—Mr. BRYANT said he did not lay any claim to novelty, but advocated the great principle of conservative surgery. The dressing he used was dry lint enveloped in cotton-wool, not with a view of excluding germs, but of keeping up an equable temperature.

GLASGOW PATHOLOGICAL AND CLINICAL SOCIETY.

TUESDAY, JANUARY 12TH, 1875.

JOSEPH COATS, M.D., Vice-President, in the Chair.

Cerebral Tumours in a Horse.—Dr. KNOX showed the brain of a horse, from a case of double amaurosis. A diagnosis of tumour in the choroid plexus had been made by a veterinary surgeon in Dublin, but the history of the case was imperfect. The lesions were a sarcomatous enlargement of the pituitary body, and sarcomatous tumours on both choroid plexuses. The pituitary body was of the shape of a ball, measuring one inch in diameter. It had exerted considerable pressure upwards on the third ventricle, optic tracts, and commissure, and outwards on the carotid arteries and venous sinuses; it thus was, without doubt, the chief cause of the symptoms observed in life. On section, it was found somewhat irregularly lobed, with loose connective tissue between the lobes; the substance of the lobes was brittle and somewhat grey; ecchymosis had taken place to a considerable extent in some of them. The enlargement was found to be due to a hyperplasia of the

normal gland-tissue; the cells, however, were larger, and contained one or more large nuclei: they were either single or in groups, enclosed in the meshes of the connective tissue, which existed in marked abundance. The tumours on the choroid plexuses were small and oval; the right rather larger than a bean, the left rather smaller. These consisted almost entirely of small angular masses of cholesterol (resembling miniature gall-stones) imbedded in loose connective tissue. The outer part of the tumours were firm, and consisted of adenoid tissue similar to that found in the pituitary body. The tumours were thus lympho-sarcomatous, and Dr. Knox was inclined to believe that they were of constitutional origin—probably connected with disease of the lymphatic system. In support of this view, he referred to a case reported by Professor Williams of Edinburgh (*Ed. M. J.*, p. 424), in which similar tumours appeared "after recovery from an attack of darcy affecting the cervical and facial absorbents".—Dr. LEISHMAN wished to know what symptoms had afforded ground for the diagnosis of tumour in the choroid plexus, as these might have a value in the human subject.—Dr. JOSEPH COATS said that, in his experience, small growths on the choroid plexus were of comparatively frequent occurrence in the human brain. These growths were mostly either cysts or psammomata, and appeared to produce no symptoms whatever, even when they reached as large a size as the larger of those in Dr. Knox's case. He felt inclined to consider these tumours in that case as simple coincidences.—Dr. ALEXANDER ROBERTSON agreed that such growths in the choroid plexus were very frequent in the human brain in all sorts of cases.—Dr. KNOX said the history was very imperfect; but he presumed the surgeon had diagnosed the choroid plexus as the seat of the tumour, simply on account of their frequency in this situation, and their extreme rarity anywhere else. Such tumours frequently existed in the brain of the horse, also apart from any symptoms.

Improved Elastic Tourniquet.—Dr. DAVID FOULIS showed an instrument he had devised, which was now made and kept by Hilliard. It supplied a want felt in applying Esmarch's elastic band, namely, a simple and efficient means of fastening the band at any point. It consisted of two connected metal tubes: one to hold the band, the other to catch it at any degree of tension. To apply it, the band is stretched across the limb, the catch being in the middle; the ends are then passed under and around the limb, and brought up and slipped into the slit of the upper tube, while on the stretch. The expansion of the India-rubber, on relaxation, fixes the ends firmly in the catch. To remove the pressure, the ends are stretched, and, while thus narrowed, are lifted out of the slit. Dr. Foulis showed various applications of this tourniquet on a patient for amputation at the shoulder-joint, upper part of the thigh, &c. He said that the elastic tourniquet prevented bleeding from the veins, as well as the arteries, without any previous bandaging of the limb being required, provided the limb were elevated for a short time before its application, so as to remove engorgement; the veins were thus converted into tubes closed at the upper end. He also said this catch allowed a relaxation of the pressure to be made gradually, so as to guide the surgeon in the tying of the smaller arteries cut at an amputation; by putting one of the turns loosely and the other more tightly, the latter could be removed at the desire of the surgeon in the picking up of the arteries. There had, however, been no opportunity as yet of testing the instrument in actual operation.—Various members tested the efficiency of the catch, and expressed their satisfaction with its simplicity and freedom from slipping. Dr. ALEXANDER PATTERSON thought such a portable tourniquet, so efficiently and so easily and rapidly applied, would form a valuable instrument for military practice on the field.

Neuroma Microscopic Characters.—Dr. ALEXANDER PATTERSON showed a small oblong tumour removed by operation from the median nerve, in the upper arm. The man had suffered from paralysis of the left forearm for eight years, and the growth was supposed to have been due to an injury. In removing it, the tumour was found quite distinct from the surrounding tissues, with the exception of the nerve which ran into it. Dr. THOMAS REID exhibited sections of this tumour under the microscope. He said that, on making a longitudinal section, traces of the original fasciculi of the nerve-substance were observed by the naked eye running through the centre of the tumour. This consisted of a soft slightly elastic tissue, with a tendency to nodulation at the surface. The microscopic sections through the centre of it showed traces of the fasciculi of nerve-fibres, principally at the smaller extremity of the tumour, which seemed the most recent portion. The interspaces of this reticulation were occupied by loose connective tissue, containing abundance of small round cells. At the other extremity of the tumour, the nervous tissue appeared to be entirely replaced by these cells. The general substance of the neuroma was made up of these cells retained in a fine stroma. From the large size of the arteries imbedded in the tumour, it must have contained much blood during life, and Dr. Patter-

son informed him it was considerably larger than the specimen as now exhibited. The tumour, although probably of traumatic origin, was evidently not composed of simple granulation-tissue, as chronic acid did not act on it as it would have acted on such tissue; the cells, moreover, were smaller than usual granulation-cells, slightly oval and highly refracting, and resembled the ordinary granules of the neuroglia in size and shape. He thought the tumour was to be classified as a sarcoma or gliosarcoma.—Dr. JOSEPH COATS regarded the case as one of false neuroma. The tumour was not composed essentially of nerve-fibres, as in certain true neuromata which he had seen; the history suggested an inflammatory origin, but he was not prepared at once to classify it exactly.

Morbid Specimens.—Dr. ALEXANDER PATTERSON showed a preparation from a fatal case of extravasation of urine. There was stricture of the urethra; and an impacted stone just behind it.—Dr. HECTOR C. CAMERON showed some urinary calculi.

MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

WEDNESDAY, JANUARY 6TH, 1875.

RUTHERFORD HALLDANE, M.D., President, in the Chair.

Exhibition of Patients, Specimens, &c.—Mr. ANNANDALE showed:—1. A little boy, on whom he had operated for Traumatic Arterio-venous Aneurism of the Popliteal Artery and Vein. He had cut down on and tied both vessels, with good result. 2. A man, whose Tongue he had removed for Epithelial Cancer. He had divided the jaw at the symphysis, and then split the organ, removing each half separately by means of the *écraseur*. 3. A lad, who had sustained a Fracture through both Rami of the Lower Jaw. As the fragments could not be kept together by any ordinary means, he had made an external incision over the fracture on both sides, drilled the fragments, and brought them together. The patient could masticate, and the deformity was not great. 4. A Goitre, which he had removed by Dr. P. H. Watson's operation without much hemorrhage, though it was partially adherent to the trachea. The patient unfortunately died of secondary hemorrhage on the night of the operation, as he would have it done in the country. 5. A preparation of Osseous Ankylosis of the Knee and Ankle-joint.

Mr. JOSEPH BELL showed preparations of Gurjun Oil in its purity, as an emulsion and as an ointment, in which forms it is used and recommended by Dr. Dougall, of the Convict Prison in the Andaman Islands, as a mode of treatment for leprosy, which, in his hands, has proved most successful. Mr. Bell gave some details as to the preparation and use of the drug, and of the excellent results which Dr. Dougall has obtained.

Dr. MCKENZIE showed a set of Electro-Physiological Apparatus made for him by Mr. Hart, instrument-maker, Edinburgh. It included: 1. Various kinds of clamp-forceps; 2. Polarizable electrodes; 3. Non-polarizable electrodes; 4. Various kinds of keys; 5. An electromotor; 6. Heidenhain's tetanometer; 7. Commutators; 8. Pflüger's hammer; 9. A new kind of electrode for experiments on the rapidity of the nerve-current.

Dr. CADILL showed a wax cast of a penis, with an uncommon form of Primary Syphilitic Lesion—*induration only, without any ulceration of the skin*. There was slight desquamation of the cuticle from the most prominent part of the induration. The resulting secondary symptoms were mild.

Bloodless Surgery.—Mr. CHIENE read a paper on this subject. It consisted of a review of Esmarch's method of operating after elastic compression of the limb, and with an elastic cord instead of a tourniquet. Mr. Chiene discussed the advantages and disadvantages of each of these plans. The gist of his remarks was, that the elastic compression was inapplicable and dangerous in many cases, from its driving back into the circulation cancer or putrid fluids; that it was too perfect, as it emptied even his smaller capillaries, and thus prevented the formation of a proper coagulum in the larger vessels. He much preferred a method which has for years been in use in the Edinburgh Infirmary, and which he believed was introduced by Mr. Lister, namely, to elevate and bandage with a common roller the limb to be removed. He also much preferred the ordinary tourniquet to Esmarch's elastic one, because the latter cannot be slackened off gradually, but must be removed entirely, so that much blood may be lost in tying the vessels.—Mr. JOSEPH BELL agreed in many of Mr. Chiene's theoretical objections to Esmarch's method. He had given it a very full trial, and believed that, while it was easily managed with good assistants in hospital practice, the old-fashioned tourniquet was much more suitable for cases in private, especially in the country, where few skilled assistants were to be had. He liked Esmarch's method much in cases of necrosis or excision of joints such as the wrist-joint, which demand careful dissection, and in

which the wound could be plugged, and thus all bleeding stopped before the elastic cord was removed. He also thought it of great advantage in all cases in which needles, splinters, bullets, etc., had to be sought for, as it entirely removed any bleeding, and also rendered the parts partly anæsthetic.—Mr. BLACK stated that in Aberdeen Dr. Keith used to bandage the limb of old people before amputation, and have them elevated, so as to empty them of blood, and thus save it to the system. He saw Esmarch's method lately in St. George's Hospital, but there they used the old-fashioned tourniquet, instead of the elastic ring.—Mr. ANNANDALE had not used Esmarch's method, and did not intend to do so.

Hydronephrosis.—Dr. COGHILL read an account of a case of hydronephrosis of the right kidney in a lady, aged 30. It had resisted all remedies; but, after a single tapping by an exploring needle, which let out four pints six ounces and a half of straw-coloured fluid, the patient recovered. He alluded to the rarity of the disease, and gave references to other cases.—The PRESIDENT expressed his interest in this case.

Jaborandi.—Dr. CRAIG read a short communication on the properties and botanical characters of the new sialogogue jaborandi. He described the difficulty he had met with in obtaining any; and detailed the symptoms he had observed on himself after taking the only dose of the drug he could procure. He took less than a drachm of the drug infused in hot water for two hours. In twenty minutes after it was swallowed, salivation commenced, and in a few minutes the mouth was literally flowing with water. Simultaneously, a perspiration appeared on the forehead and over the whole body. This continued for four hours. The temperature of the patient remained normal; that of the room being 54 to 56 deg. Fahr. The drug appeared to act by direct stimulation of the sweat and salivary glands; and it appeared to be a sialogogue of extraordinary power.

PATHOLOGICAL SOCIETY OF DUBLIN.

SATURDAY, JANUARY 23RD, 1875.

HENRY KENNEDY, M.B., and subsequently Sir D. J. CORRIGAN, Bart., Vice-President, in the Chair.

Pendulous Tumour of Mamma.—Dr. MACSWINEY exhibited a curious tumour removed from the breast of a woman, aged 50. Six years ago, at the time of the menopause, a "wart" appeared near the centre of the right breast. For a long time, the growth gave no trouble, but ultimately the skin over it became abraded, and exuded a viscid serous fluid. Mr. Kane, Surgeon to Jarvis Street Hospital, finally removed the tumour at Dr. MacSwiney's request. The pedicle was six inches in length, and sprang from the areola, close to the nipple. Dr. MacSwiney considered that it arose from hypertrophy of the sebaceous follicles of the part. He referred to Mr. O'Ferrall's paper on *Pendulous Tumours*, in the *Dublin Quarterly Journal of Medical Science* (vol. iv, 1847, p. 305 *seq.*), in which that gentleman described a precisely similar case.

Cholesterol in the Eyeball.—Mr. H. WILSON showed an eye removed from a child, aged 2½, in whom a brilliant golden yellow reflection from the eye gave rise to a suspicion of glioma, or of non-pigmented sarcoma of the choroid. The ophthalmoscope revealed a tumour which pressed from behind forwards, encroaching on the optic nerve and lens. The retinal superficies was healthy. The eyeball was removed, and cholesterol was found behind the retina, a collection of fluid between the choroid and retina being filled with cholesterol plates.

Intracranial Hemorrhage.—Dr. E. H. BENNETT presented the calvarium of a young man, aged 19, who had been struck on the head with a beam. He fell senseless, but quickly rallied after vomiting. In about two hours, he again sank into unconsciousness, hemiplegia occurred, and he died seven hours and a half after the receipt of the injury. A fracture ran downwards from the coronal suture, through the temporal fossa, to be lost in the zygomatic fossa. The dura mater was extensively detached from the bone, and an immense clot of blood filled the intervening space. The source of the hemorrhage was the meningeal artery, which was torn through two-thirds of its circumference. The separation of the dura mater had evidently permitted the great hemorrhage, which in turn induced fatal compression of the brain.

Fatty Degeneration of Heart.—Dr. H. KENNEDY showed a specimen from the body of a woman, aged 80, who had presented the phenomenon of "Cheyne-Stokes's respiration", with a pulse of 66, but without any abnormal cardiac sound. On this last point, Dr. Kennedy laid particular stress, as valvular degeneration, in his opinion, by no means frequently accompanied general fatty degeneration of the heart. In the present case, the right side of the organ was almost entirely fatty.

Fatal Obstruction of the Intestines.—Dr. J. K. BARTON showed the intestines of an old man, who suffered from constipation for four weeks.

When admitted to hospital, his belly was much distended, yet there was but little tenderness on pressure. The pulse was quick and weak. The right side of the abdomen was dull on percussion. After a calomel purge, fluid feces escaped freely, but no solid matter passed. Vomiting set in, and finally Dr. Barton punctured the intestine with a small trocar and cannula. No great relief followed, and colotomy was performed on the right side. The patient was at once relieved, but sank from shock after a few hours. Extensive peritonitis was found, and an obstruction existed at the junction of the ascending and transverse colon. A constriction extended for three inches in this situation, and the pyloric orifice of the stomach was also surrounded by the same hard and rigid fibrous material, which had evidently been developed in the submucous connective tissue. Microscopically examined, the mass was proved to be of lymph origin.

Rupture of Posterior Part of Liver by Force applied anteriorly.—Mr. JOHN HAMILTON laid on the table the liver of a boy, aged 19, on whom a wall had fallen. He was taken into hospital collapsed, but without any external mark of injury, excepting a cut on the chin. He rapidly died. All the viscera were uninjured except the liver, which had been extensively lacerated. The Spiegelian lobe was torn away; the surface of the organ was bruised; in the lobulus quadratus there was a deep rent; there was an abrasion on the right posterior aspect, and close by a deep rent almost divided the liver into two parts. Twenty-six ounces of blood lay in the peritoneal cavity. It was clear that the force applied anteriorly had not been resisted by the soft parietes and yielding liver; hence the absence of injuries in front. But the hard spine had acted as a counter-force, and so had torn the posterior surface of the liver when violently dashed against it.

MANCHESTER MEDICAL SOCIETY.

DECEMBER 2ND, 1874.

JOHN GALT, F.R.C.S. Eng., in the Chair.

Molluscum Fibrosum.—Dr. LEECH showed a specimen of molluscum fibrosum, occurring in a mother and daughter. The face and neck were the parts principally affected. Both patients were attacked at or about the same age. Dr. Leech had examined microscopically some of the small growths, and found them to consist of hypertrophied connective tissue.

Treatment of Nævus.—Mr. CULLINGWORTH exhibited two patients, illustrating the treatment of nævus by Dr. Geiger's method.

Chronic Albuminuria.—Mr. JONES exhibited the kidneys from a case of chronic albuminuria. Besides general ana-æmia and ascites, the patient had double hydrothorax, hydropicardium, and right pneumonia. The right kidney weighed six ounces, and the left three ounces. Both organs were lobulated and extremely anæmic, and the left was only about half the size of the right. The great difficulty in this line seemed to be, to determine whether the organs were originally of different size, or whether the smaller one had undergone contraction.

Diseased Liver and Ascites.—Dr. W. ROBERTS exhibited the liver from a patient who died with ascites. The history of the case was briefly as follows. E. M., aged 19, was admitted into the Manchester Royal Infirmary, on September 18th, for the second time. The abdomen was enormously distended with fluid. The superficial veins were very prominent; there was no swelling of the legs. The liver could not be felt. The urine was normal. Paracentesis abdominis was performed, and twenty-five pints were evacuated. She had been tapped twice during her previous stay in the infirmary, and forty-five pints of clear straw-coloured fluid drawn off. After the last tapping, peritonitis set in; and she died three days after the operation. The liver weighed thirty ounces. Its surface was smooth; the capsule was thickened and adherent to the diaphragm and abdominal parietes. The organ was anæmic; and the lobules were very distinctly mapped out and surrounded by thickened connective tissue. The spleen was much enlarged, firm, and weighed twenty-seven ounces. There were old cellular adhesions on the right side of the chest, more especially at the base. The intestines had a sodden appearance, and were matted together by recent lymph. Dr. Roberts explained the atrophy of the liver by extension of inflammation that had existed in the right pleura through the diaphragm to the capsule of the liver, and thence invaded the connective tissue of the organ itself. In confirmation of this view, he related a case mentioned by Dr. Macleod in his work on the liver.

Amputation of the Scalp.—Mr. BOUTFLOWER again showed a case in which the entire scalp had been torn off by machinery; and in which the skin had been successfully reproduced by means of transplantation.

Capsulated Scirrhus of the Breast.—Mr. CULLINGWORTH read a short paper on a case of capsulated scirrhus of the breast. A cordial vote of thanks to the reader of the paper brought the meeting to a close.

SELECTIONS FROM JOURNALS.

THERAPEUTICS.

INFUSION OF MYRTLE AS A REMEDY FOR LEUCORRHOEA.—M. Delion de Savignac believes that myrtle, which contains both essential oil and tannin, is well indicated for leucorrhoea. As myrtle-flowers only contain the essential oil, whilst the berries and the leaves contain both essential oil and tannin, he recommends the employment of the latter. He uses them as an infusion, pouring a *litre* of boiling water on ten *grammes* of the leaves or berries. If a very powerful astringent action be required, from twenty to thirty *grammes* of the material must be used. The infusion, when used, must be cold or slightly warmed, copiously employed to the quantity of four or five pints, and should be carried up as high as possible.

TREATMENT OF PERTUSSIS BY INHALATION.—Dr. J. Winthrop Spooner, in the *Boston Medical and Surgical Journal*, Nov. 5th, 1874, details the results of his experience in eleven cases of whooping-cough treated by the plan recommended by Dr. John J. Caldwell of Baltimore in the number of that journal for April 20th, 1874; viz.: R Fluid-*ext. belladonnæ* miv ad x; potass. bromid. ℥j; ammon. bromid. ℥ij; aquæ ℥ij. Inhale one tablespoonful in an ordinary steam-atomiser. Dr. Spooner uses a tablespoonful of this mixture, and fills up the glass of the atomiser with water. When the disease is at all severe, he uses the atomiser twice daily until the urgency of the symptoms is relieved, and then continues it once daily until the cough has entirely disappeared. In some cases, he has somewhat varied the proportion of the ingredients, but has made no essential departure from the formula given. The effect of the method shows itself immediately; and, besides the prompt relief of the distressing symptoms, the period of the disease itself is much lessened in the majority of cases. In only one of the eleven cases was any other treatment than that by inhalation used; and the apparent failure in this case seemed to be due to the difficulty in maintaining the remedy thoroughly, on account of the age of the child—only two years old. *Brit. Med. Journal*

QUININE AS A PROPHYLACTIC AGAINST ERYSIPELAS.—Dr. Y. R. Le Monnier, Visiting Surgeon of the Charity Hospital, New Orleans, in the *New Orleans Medical and Surgical Journal*, November 1874, considers quinine, until otherwise proved, as a preventive of the erysipelas which often follows wounds. "When the disease is epidemic," says Dr. Gross, "it often shows itself within a very short time after the receipt of an injury, however slight." In Dr. Le Monnier's ward, the disease raged for five months, during which time he dared not operate, unless in cases of immediate necessity. In one case, a patient was operated upon for fistula of the anus on April 10th, and on the morning of the 21st, he had erysipelas at the site of injury. He had to operate on another patient for fistula of the anus on the same day, and there were three cases of the exanthem in the standing beds. He then prescribed quinine as a prophylactic for the first time (two grains every two hours; afterwards three times daily). The patient was in the infected ward for seventeen days, his wound progressed satisfactorily, and he was discharged cured without having had erysipelas. Dr. Le Monnier continues: "From this day I gave quinine in two-grain doses three times daily to all the patients upon whom I operated, and have not had any new cases among them." One patient to whom I did not give it, not thinking it necessary, was taken sick with the disease [erysipelas of the anus] May 1st, 1874." He promptly to manipulations for gradual dilatation of a structure of the rectum.

MEDICINE.

SUPPRESSION OF URINE.—The following cases of prolonged suppression of urine are given in the *Transactions* of the Maine Medical Association, 1874, as having been reported at some of its meetings. Dr. F. C. Wiley of Bethel reported a case of entire suppression of urine for thirty-seven days, with recovery. Dr. B. E. Barton of Warren reported the case of a woman, thirty years of age, very fat, and subject to a mild form of eclampsia of an epileptiform character. When seen, she had violent pain, which, she said, was nearly as severe as labour. She had passed no urine for twenty-four hours. He introduced a catheter, but found no urine in the bladder. He gave her diaphoretics and opiates. He saw her the next day, and told her she had passed no urine. On the ninth day, Dr. Estabrook saw her with him, and they both expected a fatal result. At the end of ten and a-half days, she passed a

large quantity of urine from the bladder, which seemed normal in quality. From that time, she made a good convalescence. During all this time, there was no symptom of blood-poisoning, and no vicarious action of any other organs; there was no urinous smell; her bowels were constipated, and the skin was flushed. Dr. A. S. Thayer of Portland reported the following case. A child had scarlatina, which ran its usual course for three weeks, when there was suppression of urine. She passed about one drachm the following night. There was considerable anasarca; she was nervous and sleepless, and the stomach was irritable, but there were no convulsions. At the end of exactly one week, she passed about an ounce of urine, and made a good convalescence. Dr. G. F. French of Portland reported a case of a girl, eighteen or nineteen years of age, very hysterical, in which there was complete suppression for seven or eight days, and then but a small amount was passed. This was repeated at three different times at varying intervals. She also abstained from food for three weeks.

PERITONITIS WITH PERITONEAL EFFUSION: TAPPING; RECOVERY.—Dr. A. J. Fuller of Bath, United States, reports the following case (*Transactions* of the Maine Medical Association, 1874). Mrs. S., aged 28, previously healthy, was attacked on the night of May 12th, 1872, after walking some distance exposed to cold night air; all the usual symptoms of peritonitis were present, high fever, tenderness and swelling of the abdomen, with constipation. Dr. Fuller saw her on the 13th, and pursued an active antiphlogistic treatment, combined with alteratives and sedatives. On the 19th, she was so far recovered that he discontinued his visits. On May 24th, he found the abdomen largely distended; no pain or tenderness; she felt quite well. There was fluctuation over the whole abdomen, having all the appearance of serous effusion. The distention had been very rapid, without any perceptible constitutional disturbance. Such remedies as were indicated were employed, without the least improvement. There was no perceptible change for six weeks; then some slight chills, with prostration, appeared. Feeling that further delay would be detrimental, Dr. Fuller operated July 10th, and, on withdrawing the trocar, it was followed by a full stream of six quarts of pure pus. The wound was dressed with cotton-wadding, secured by adhesive straps. In the following three weeks, Dr. Fuller drew five quarts more of pus at different times—the original wound never healing until all was removed. This large drain rendered the patient somewhat anemic, with loss of strength. With tonics and generous diet she soon began to recover, and seemed to fully regain her health. The interesting point is, that so large a collection of pus should form suddenly with so little constitutional disturbance. *Brit. Med. Journal*

SURGERY.

TARLAVAN AS A BANDAGE AND DRESSING FOR WOUNDS.—Dr. A. B. Cook of Louisville, in speaking of the value of this material (*American Medical Weekly*, Dec. 20th, 1874) in the treatment of wounds, says that its advantages are, that it is "cheap, light, transparent, cool, and comfortable; it is so open in texture, that it secures the daily inspection of the wound or diseased structure, without the necessity of removing the dressing or disturbing the patient—two things much dreaded by the sick. It does not interfere in the least with the local application of poultices, water, or medicated lotions; it gives free exit to pus and other exudates; sinuses and abscesses can be injected by passing the nozzle of a syringe through the meshes; the wounds or diseased parts can always be cleansed, and, if necessary, deodorised, by passing a moist sponge lightly over the bandage. The bandage must be cut of the required length with scissors."

TREATMENT OF CANCER BY ARSENICAL PASTE.—Dr. Daniel Lewis of New York contributes to the *American Practitioner* (December, 1874) the results of ten unpublished cases of cancer treated by Marsden's arsenical paste, viz.: R Arsenious acid, 5j; mucilage of gum acacia, 5j. Mix into a paste too thick to run. Of three cases treated by Dr. Crandall, Andover, New York, one patient, a male, aged 69, "lived two years without recurrence (of the epithelioma of two years' standing below the left ear), when he died of some cardiac affection"; the second patient, aged 50, with epithelioma on the right cheek, still remains well after five years; and the third, a male, aged 62, with medullary cancer of the vertex, continues well after two years. Dr. Lewis reports seven cases treated in the same way by himself, with uniformly satisfactory results; and two cases by Dr. Foadyce Barker, one "without recurrence after four years, and the other with recurrence after one year, when the knife was used, but with what result is not known."

BRITISH MEDICAL ASSOCIATION: SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, FEBRUARY 6TH, 1875.

MEDICAL ADVERTISING.

MR. JAMES LANE's address, of which we recently published an abstract, is, we hope, likely to give rise to some further consequences. The remarks which he made on medical advertising are repetitions of similar observations which have been many times made with more or less force and clearness, and with more or less authority. The most important official utterance was that of the London College of Surgeons. This College some time since passed a resolution condemning the practice, and the College of Physicians endorsed it.

The general result of all that has been done and said cannot at this moment be highly estimated. There is, as far as we see, an unanimous assent that medical advertising, as now carried on in the daily papers, is an evil; and that the cat should be belled. But who is to bell the cat? The College of Surgeons disapprove; but their disapproval is in a vague general form, which does not materially touch the conscience of any individual, and has not had the least effect. The leaders of the profession disapprove; but the names of Sir W. Jenner, Sir H. Thompson, Dr. Barnes, and others, were advertised lately, without their knowledge, across three columns of the back page of the *Poll-Mall Gazette*, by a medical newspaper which has been particularly energetic in denouncing medical advertising (at the same time that it has practised it at all the railway book-stalls). A well known medical publisher of high repute followed the example; and, a few days afterwards, the back page of the same evening paper was ornamented by other names of medical men and the subjects of their writing, printed across three columns. What the *Lancet* had done, Mr. Macmillan might repeat; and the names of Dr. T. L. Brunton, Dr. George Johnson, Dr. Roberts, Dr. Broadbent, Dr. Basham, Mr. Power, and Mr. Brudenell Carter, were presently brought into the same public prominence and in the same place as those of Sir William Jenner and Sir Henry Thompson. If we mention names in this describing an example of medical advertising, it is because we think that it is only by living examples that the dead words of a vague resolution can be galvanised into life. They import no element of unpleasant personality; for we are not aiming at distributing critical censure, but only at holding a mirror up to existing facts, and placing realised facts in contrast with ideal resolutions. No journal has been stronger in denouncing medical advertising than the one we mention, which even went so far as to blame a London physician by name for allowing copies of his works to lie upon the table of his waiting-room. Nevertheless, it avails itself of placards and railway-bills to announce to gaping railway-passengers the names of medical men who deal with all sorts of subjects which are to the multitude *curious*, and to the laity *unclean*. The names we have quoted are those of distinguished men; yet we find them, owing to the act of the oldest medical journal, and of the most respectable of publishers, figuring prominently in a half-page advertisement across the back of a leading evening paper.

We are obliged to conclude that vague resolutions as to "excessive" advertising are without evident force or definite meaning. It is difficult to say how professional advertising, as such, could be carried to a

greater extent than in big capitals across the back page of a daily paper. It used to be said, that "excessive" advertising means the advertising which a man did for himself; and "legitimate" advertising means the advertising which somebody else did for him. Thus, if a medical work were advertised only in "the publishers' column" of the *Times* and *Daily News*, or in the periodical column of a medical publisher in the political and literary papers, that would be a "legitimate" advertisement; if the author himself "took the advertising of his book in his own hands, and if it appeared, therefore, in other parts of the paper, such as what is sometimes fairly enough called 'the quack's corner,' or alone anywhere", that would be excessive advertising. Such a classification is very faintly plausible regarded at the first blush. A moment's examination, however, disposes even of its plausibility. There is no reason why a medical author should allow his publisher to select the places and prices of advertisement; that may easily mean, that he pays twenty per cent. more than he need to pay for all his advertisement, and that many of them appear in places where it is to the publisher's rather than to the author's interest that they should appear. Some of the most distinguished of our medical authors choose to retain their copyrights, and to manage their advertising for themselves. Their advertisements in the daily papers will then appear out of the regulation column. This, therefore, is a classification of advertisements which will not bear a moment's inspection. Moreover, in both the cases to which we refer by way of example, as being the most recent and striking which have come under our notice, the advertising is done on the authority of a medical publisher or medical editor.

Now, here are two questions left for decision which are pretty sharply defined, and which it may not be inopportune to attempt to obtain solution. Are Sir William Jenner, Sir Henry Thompson, and Dr. Lauder Brunton, and the other gentlemen whose names we mention, disposed to approve and vindicate the advertisements in which their names appear? If they are, it would be desirable to know it, and we should attach great weight to their opinion even while differing from it. In that case, the resolution of the College of Surgeons, which was, we rather think, endorsed by the College of Physicians, will go for very little, and the observations of Mr. James Lane must be accepted under special interpretation. The discussion will be then left where it began, before any *ulterior dicta* had been pronounced.

Do they disapprove of it? We are disposed to hope that they will inform our readers that they disapprove of these advertisements. We reach, then, a further point. It will then become evident, that neither the experience of the most ancient and loudly protesting medical paper, or the judgment of the most eminent of publishers, can be trusted to define propriety in advertising medical contributions and medical works in daily papers. Still less, as we all know, can we trust the taste and self-restraint of individual authors of various degrees. The standard is gradually lowered by fine degrees, until, at last, it falls very low indeed.

The final conclusion is not hard. It is no less than this: that, in medical advertising, British medical authors and publishers must conform to the rule which is current in France (we believe, indeed, everywhere in Europe) and in America. This may be severe, but it cannot be intolerable; since it is the rule of propriety universal amongst medical men in every other civilised country in Europe. The physician, the surgeon, the general practitioner, who, in France or in America, should advertise, or allow to be advertised, his medical works in a political paper, or in any other than a medical paper, would at once indicate that he resigned his pretensions to professional respect, and that he accepted professional ostracism.

Is it not, indeed, without meaning that books addressed only to technically educated men—books unintelligible, and, if unintelligible, therefore offensive to the eyes of ordinary people—should be

announced at the breakfast-table?—that the young lady who looks for the last new novel, or the latest announcements in music and literature, must perforce read of “the diseases of the genital organs”, “the pathology of the testicle”, the “painless cure of gonorrhoea”, the means of fecundation, and the cure of sterility? There are certain medical authors who avowedly address books for good and useful reasons, to non-medical readers; those will, of course, take their place, as before, among avowedly popular books. We are not speaking of these, but of purely medical works for medical readers. We say that there is no reason in the world why these should be advertised in the daily papers: no reason, of which we know, which has ever been advanced. There are, indeed, as Mr. James Long very plainly states, pecuniary motives which may render such a course advantageous. The same motives would justify painting a van or blowing a horn. They are motives which are only respectable when restrained by the sense of usefulness and propriety. We wish, then, now broadly to raise the issue: Shall medical advertising in the political papers be recognised in this country as a lawful professional proceeding, or shall it be discontinued? And as some very distinguished professional men have lately been included—by no act of their own—amongst those whose latest medical writings have been so advertised with extraordinary prominence, and as we have frankly mentioned them, and now candidly appeal to them for their views, we are not without hope that they will help us in the solution of what is really by no means a trifling professional difficulty.

AN OBSTACLE TO ARMY MEDICAL REFORM.

It is impossible to read the letters which reach us from time to time from our army correspondents, without perceiving that there is one very serious obstacle in the way of effecting anything like a marked improvement in the consideration attached to the army medical service at large by the authorities at the Horse Guards and War Office, and, as a consequence, in the status and welfare of the medical officers individually, which would be sure to follow such increased consideration if only it could be attained. There is a remarkable want of unanimity among the army medical officers. A very large proportion of them seem to desire a change in the organisation of their department; but, as to the particular change which is to be desired, the most opposite opinions are expressed. Even with respect to the fundamental arrangements for conducting their hospital duties, and to the relations which should exist between themselves and the combatant officers of the army, they hold very different views. There is not a corresponding want of agreement in the views and aims of the naval medical officers on fundamental questions; and, as they are thus free from important differences among themselves, they are able to combine their energies and to devote them to a common end. The attainment of success in their objects is, therefore, a far more probable event than it is as regards those of their brethren in the army. No doubt, the efforts of the naval medical officers and their friends are strongly assisted by the fact that there is a dearth of aspirants for commissions in the naval medical service; but still the naval officers have an advantage in all pulling together, which the divergent views, and apparently the divergent interests, among their brethren in the army prevent them from having. Nor is the want of agreement, to which we refer, to be found in the executive ranks only; different views respecting departmental organisation are put forth, and their adoption is strongly urged as the only means of restoring content in the department, by medical officers of wide experience, some of them, indeed, holding the most prominent positions in the administrative ranks.

From all that we can gather, the army medical officers seem to be split up into three distinct parties as regards the conflicting views under notice. One party demands a complete return to what is called the *regimental system*, or, to designate it more correctly, the mixed regimental and staff system. Under this system, part of the medical

officers would be gazetted and belong permanently to regiments, while part would form a special body, the members of which would be available for services of all kinds, as was formerly the case. A second party, in opposition to the system just named, presses for a *general corps system*. Under this system, all the medical officers constitute a single corps, and are employed on duty wherever their services are required, whether with regiments or elsewhere. This seems to have been the principle of recent regulations affecting the army medical service, but it is stated that the principle has been only imperfectly applied. It is also said that what has been done has been done in such a way as to neutralise the advantages which would have resulted from it, if the principle had been applied judiciously and with due consideration for the officers affected by the change. The third party is striving for the reintroduction of the *regimental system*, but in a modified form. Under this plan, the regimental system is to be reverted to in time of peace so far as regards medical officers belonging permanently to regiments, but their patients are to be treated by them in station hospitals instead of regimental hospitals; while, in time of war, medical officers are to be liable to be moved from their regiments as if they formed a general medical staff.

Many reasons are given in favour of each of these three systems. The leading arguments put forth may be summed up as follow. For the first, or regimental system, it is alleged that the greatest inducement which the army medical service formerly offered to a student was the fact that, at the outset of his start in life, the army surgeon occupied, owing to his regimental connections, a social rank which it takes the civil practitioner years to attain; that by its means he acquired early competency; that, from the alteration of the system, the army medical service has suffered, because men of inferior stamp only can be induced to enter it; and that the *prestige* of the medical profession is essentially lowered in consequence. It is further urged that, almost all combatant officers being in favour of the separate existence of regiments, medical officers should necessarily form an inseparable part of them; that medical officers so placed become identified with regimental interests, become acquainted with the constitutions of the men, and prevent malingering; that, in war, the regimental hospital system is best, because regiments need medical officers of their own then more than at any other time; that general hospitals are general evils; that departure from the regimental system entails an enormous increase in the charges for the conveyance of the sick and their guides to general hospitals, in the erection of new buildings, and other ways; that a thirst for military command is in full force in the unification scheme, while the reasonable authority of medical officers is most fully supported in regiments; that the regimental system prevented the frequent changes of station and other intolerable inconveniences associated with them, which are sources of discontent and unhappiness among medical officers.

In favour of the second, or general corps system, it is contended that the old regimental hospital system, with its independent hospitals and hospital equipment, has been proved to be impracticable in war time, and that in warfare of the present day, in which armies move so rapidly, it is more than ever so; that in campaigns the sick must be treated in general hospitals, and though some medical officers must always be with regiments, the bulk of the medical officers can be most serviceably employed in hospitals where patients from all corps can be equally admitted; that, as armies are only kept up for service in war, all parts of an army should practise in peace time the system which must be used in war; that the cost of regiments transporting their own hospital establishments from station to station throughout England and Ireland was found to be excessive, while this costliness is greatly lessened by the system of station hospitals; that patients in general hospitals obtain the same advantages which patients in civil hospitals derive from greater observation of their cases, from mutual consultation and help by the medical staff; that the medical officers are benefited by having a wider sphere of professional observation than they can have in small isolated hospitals; and that general hospitals, like regimental hospitals, are good or bad, according as they are well or ill supervised and con-

ducted. As regards the medical service in its character of an army department, it is stated that a system which forms the medical officers into a single corps, puts all the medical officers on a more equal footing in respect to home and foreign service, changes of station and duties; and that another advantage of it is, that it is likely to engender, in course of time, an united feeling, and to create for the medical officers the same professional weight and authority as is found in other scientific corps of the army, but which can never be looked for under a system of division with divided interests and advantages.

For the third, or modified regimental system, these advantages are claimed. There would be a better division of duties; the regimental surgeon-major would do duty in the station hospitals, treating his own men in contiguous beds and wards as far as practicable, while the juniors would do the barrack duties, examine prisoners, and attend women and children; the younger medical officers would acquire habits of discipline and learn routine duties under their seniors; the establishment of station hospitals, having permanent surgeries, would obviate loss or destruction of property by its conveyance from place to place; the medical officers would again have all the advantages of regimental life secured to them permanently in time of peace, while their severance from regiments in time of war would be only temporary; the soldiers would like it better, for they would always find one regimental doctor ready to interest himself in their welfare; the system would meet all the requirements of war as well, or better, than any other plan.

Such are the leading arguments advanced to induce those in power to organise the medical branch of the army on one or other of the above named plans. We do not pretend to be able to reconcile these conflicting views, even if we had time or space for the discussion of the numerous topics that are involved in them. A more intimate acquaintance with the technical details of the army medical service is required for such a task than any outsider can possess. But is there no one in the department itself of influence enough, no one gifted with sufficient power of logical reasoning and utterance, to evoke concord out of this discord? Can it be true, as some assert, that there are medical officers so wrapped up in their own personal interests, that they will listen to no reasoning that appears to be at all adverse to them, nor accept any compromise, though the common good may be ensured by it? We do not believe it. We know there must be difficulties in the way of obtaining a full settlement of such diverse aspirations, but we can hardly believe that these difficulties may not be overcome; at any rate, if differences must exist, they need hardly be forced into notice so much as they are. Of one thing we are certain, that a show of greater unanimity of views and feeling is not a matter merely to be wished for, but that it is one the attainment of which is of essential importance, if there is to be that real improvement in the professional influence and circumstances of the army medical officers which their best friends desire for them, and which, more than all others, their civil brethren of the British Medical Association, as is well known, have endeavoured to obtain for them.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

THE unconfirmed minutes of the last meeting of the Executive Committee, amongst other resolutions, contain the following:

That the *Medical Register* for 1875 be published; that 3,000 copies be printed; and that it be left to the Treasurers and Registrar to determine what number of copies should be bound.

That the list of public officers and functionaries supplied by Government with copies of the *Medical Register* be the same as for last year, with the addition of the Scottish Procurators Fiscal, fifty-three in number, as recommended by the Home Office. (See Minutes of Meeting of Executive Committee, October 22nd, 1874, vol. xi, pp. 36-7.)

A letter was read from Mr. Danby P. Fry, Assistant-Secretary of the Local Government Board, in reply to a letter from the Council, which directed the attention of the Local Government Board to the Regulation contained in Article 178 of the General Consolidated Order, requiring

that the certificate referred to in that Article shall be given by a medical practitioner, who is a Member of the Royal College of Surgeons of London, or a Fellow or Licentiate of the Royal College of Physicians of London; and, drawing attention to the objections which exist to such a restriction, having regard to the fact that the Medical Act, 1858, was passed with the view of abolishing any distinction between the legal qualifications of medical practitioners.

The reply was to the effect that the Board have had this matter under their consideration, and, having in view the provisions of the Medical Act, it seems only reasonable that the restriction contained in Article 178 of the General Consolidated Order should be removed. When that Order is revised, for which an early opportunity will be taken, the Board will bear in mind the suggestion of the General Medical Council on this subject. The Board desire, also, to point out that the Order referred to was issued in 1847, before the passing of the Medical Act, 1858.

The Registrar was requested to apply by letter to the Royal College of Surgeons, and the Queen's University, Ireland, requesting that they will make their returns without further delay; and it was resolved that 5,100 copies of the addition to the *Pharmacy Act* of 1874 be printed forthwith.

THE Prince of Wales has promised to preside at the forthcoming anniversary festival in aid of the German Hospital.

IN the report of the Pathological and Clinical Society of Glasgow, which we publish in another column, will be found a short notice of a very useful and ingenious improvement on Eschsch's apparatus for bloodless operations, which was highly approved by those present, and deserves the attention of surgeons.

COLLECTIONS for the hospitals were made in all the places of worship at Sheffield last Sunday. The amount received, according to the returns at present sent in, is £1,700, and it will be augmented by collections not yet announced. The sum obtained last year was £1,796.

THE return to Gainsborough of four men, who had been imprisoned for non-vaccination of their children, was this week made the occasion of a public torchlight demonstration. The men headed the procession, wearing their prison-dress. Subsequently, at a meeting, they were presented with a silver cup.

THE late Emperor of China died, it is stated, after eleven days' illness, from an attack of small-pox, which is making great ravages in Peking. The help of foreign medical men had been persistently refused, and the Emperor was attended only by his chief physician, Nona-Tzen.

LIVERPOOL MEDICAL INSTITUTION.

THE following gentlemen have been elected Officers and Council for 1875. *President:* Mr. McChesne. *Vice-Presidents:* Mr. T. Shadford Walker, Dr. Davidson. *Dr. Scales, Dr. Desmond. Treasurer:* Dr. Osley. *Secretary:* Dr. Lyster. *Secretaries of Ordinary Meetings:* Dr. Glynn. *Librarian:* Dr. William Carter. *Other Members of Council:* *Dr. John Bligh, Mr. Edgar A. Browne, Dr. W. Macfie Campbell, Dr. Caton, *Dr. DeLisle, Dr. Grimsby, Mr. Harrison, Mr. Newton, Mr. Rushton Parfitt, Mr. Percy, Dr. Turnbull, Dr. Waters. Those marked * were not in office last year.

THE ROYAL UNITED HOSPITAL, PATEL.

THE annual meeting of the subscribers and friends of this hospital took place on the 26th ult. The reports read showed that the income for the past year from all sources amounted to £4,700, and the expenses to £4,769. The number of in-patients during the year was 1,018, giving a daily average of 75.10. Each patient was in the hospital, on an average, 26.94 days. The out-patients numbered 8,900.

being an increase of 525 more than in 1873. Two wards had been set apart for the treatment of such infectious diseases as might occur after patients had been received into the hospital; and the Committee were requested to consult with the sanitary authority with a view of providing suitable premises for the reception of contagious diseases. Dr. Falconer was unanimously elected President of the Hospital, and the proceedings terminated with the usual vote of thanks to the Mayor for presiding.

THE ROYAL NATIONAL HOSPITAL FOR CONSUMPTION.

THE Governors of the Royal National Hospital for Consumption and Diseases of the Chest recently held their annual meeting, when it was stated that very great and satisfactory progress had been made during the past year. Two memorial houses had been given, one by the Baroness Meyer de Rothschild, and the other by the Earl of Strafford. These make sixteen houses, either complete or in course of erection; but it is found that, for practical working, two subsidiary blocks or houses are urgently needed for the temporary residence of patients awaiting their turn of admission into the hospital proper. The sum of £1,500 has been presented for the erection of one; and help is needed for the purpose of commencing and finishing both these auxiliary houses, as well as for providing a laundry, bakery, sea-baths, and farm-yard buildings. The annual income of the hospital amounts to £500, and this was supplemented last year by the Brackenbury and Ratnay legacies. The income is, however, insufficient to carry out fully the objects the Committee have in view; and they are burdened with a debt of £2,000 on their buildings. With a view of increasing their funds, a bazaar will be held in May next. Mr. Sampson Copestake was elected Treasurer, in succession to the late Mr. Henry Leaf.

ABUSE OF CHARITIES.

A WRITER in a popular periodical gives his experience of the inconceivable meanness people will stoop to to obtain medical advice for nothing. "There might be some excuse in the prevalent opinion that the most eminent men are selected to see patients at special and other institutions; but the same practitioners can be consulted at their own homes—and, as a matter of fact, the well-to-do impostors who obtain gratuitous relief are not grateful enough even to send a denotation to the institution. Shall I ever forget meeting, at an assembly at the Mansion House, the wife and daughters of an alderman, who had come to me disguised in shabby apparel to seek advice at an hospital where I had recently been appointed surgeon."

LECTURES AT THE ROYAL COLLEGE OF SURGEONS.

PROFESSOR WILSON, F.R.S., commenced his course of six lectures on Dermatology in the theatre of the Royal College of Surgeons on Monday last. The following is the syllabus of Mr. Wilson's lectures. General classification of diseases of the skin under three heads—*inflammation, nutrition, and innervation*. Preceding courses devoted to diseases of inflammation and part of those of nutrition. Diseases of nutrition are: *dystrophic, atrophic, and hypertrophic*. Dystrophic affections include: *lepra, struma, lupus, lymphoma, xanthoma, and epithelioma*. Atrophic affections: *dermatomyositis, ichthyosis, scuriosis, strie atrophice, morphea, and scleriosis*. Dermatoxerasia, its relations with ichthyosis and scuriosis; therapeutic considerations. Strie atrophice, morphea, and scleriosis: their pathology and therapeutic treatment. Hypertrophic affections: *verruca, horns, and concretions, corns, angioma or vascular naevus, areolo-fibroma, areolo-fibrous tumours, and fibrous tumours*. Verrucae, their pathology; pathology of horns and concretions; therapeutic treatment of verrucae; pathology of corns and their treatment; pathology and treatment of angioma. Pathology of areolo-fibroma; the best man; remarkable cases of dermatomyositis; hypertrophic nose; sponge; Eozenoid; elephantiasis Arabum, therapeutic management. Areolo-fibrous tumours: *acrochordon; spilus or tegumentary naevus; molluscum; fibrous tumour; cheloma*; therapeutic considerations. Disease of innervation: *pruritus; prurigo; neuropathic excoriations; hemorrhagic stigmata*;

illustrative cases: *Louise Lateau's case*. Hyperaesthesia; anaesthesia. —Professor Parker, F.R.S., will commence his course of eighteen lectures on the Structure and Development of the Skull, in continuation of his course of last year, on the 15th instant.—The lectures of Professors Lee and Turner will be commenced some time in June next.

"THE GREAT AMERICAN DOCTOR."

ON January 27th, an adjourned inquest was held upon the body of a man whose death has caused some little stir in Liverpool. The circumstances of the case are briefly these. Edward Manratty, a sheetor employed on the railway, died somewhat suddenly on the 13th ult. For about four months, during the early part of his illness, he had been attended by Dr. Bligh; but he subsequently consulted a man named Tumblety, who calls himself "the Great American Doctor". This man undertook to cure him for fifty shillings, but afterwards reduced his price to thirty shillings. This sum was paid by Manratty's wife, who received in return some pills, herbs, and a mixture, with directions as to their use. The deceased took a tablespoonful of the mixture, and died the same night. Tumblety was then asked for a certificate of death, but denied all knowledge of the case, and returned the thirty shillings to Manratty's wife. Application was next made to Dr. Bligh, but he refused to give a certificate, and very properly reported the case to the coroner. An inquest was held on the 19th ult., and was adjourned in order that the contents of the stomach might be analysed. But little information seems to have been obtained, either by the *post mortem* examination or by the chemical analysis; and no indications were found which pointed to the administration of poison. Dr. Bligh himself said, after the examination, that, if required to certify as to the cause of death, he should attribute it to disease of the heart and lungs. It was asserted, in Tumblety's defence, that he did not wish to have anything to do with the case, and put a prohibitory price upon his drugs; but the deceased and his wife had such confidence in him, that they would have his advice, cost what it might. The coroner, in summing up, commented in strong terms upon the inhumanity of a man taking thirty shillings, under such circumstances, for what, in all likelihood, was not worth thirty pence. He could only describe Tumblety's conduct as an eagerness to obtain money which could not be too strongly condemned. The jury returned a verdict to the effect that the deceased died from natural causes, but whether his death was accelerated by the administration of the mixture supplied by Tumblety there was no evidence to show. The jury also strongly censured the conduct of Tumblety in administering medicine, he being in total ignorance of the condition of the patient. In such a case as this, it was highly important that an inquest should be held. The circumstances attending the death were sufficiently suspicious to call for thorough investigation. We cannot help wishing, however, that the inquiry had proceeded a little further, and that steps had been taken to ascertain the real medical standing of the so-called "Great American Doctor". It would have been well if Tumblety had been called upon to produce the "documentary evidence" in his favour of which his counsel spoke, in order either to substantiate his position as a qualified practitioner, or, failing this, that his pretensions should be exposed and his true character made public.

LEGISLATION IN PRUSSIA REGARDING TRICHINISED MEAT.

THE Superior Tribunal in Berlin recently decided that the seller of meat containing trichinae was not liable to the penalties provided for the sale of unwholesome food, unless he knew that the meat contained trichinae, or unless his ignorance were due to negligence. A deputation of medical and scientific men consequently urged on the Ministry the importance of making obligatory, through the whole of Prussia, the examination of meat, especially the microscopic examinations of all pigs killed, and of the portions of flesh of dead pigs imported from abroad (American bacon). The Ministry has accordingly addressed a rescript to the district authorities, in which, while professing their inability to comply with the suggestions of the deputation to their full extent, they urgently recommend that the microscopic examination of meat should be rendered obligatory by police regulations, so far as the

circumstances in the respective circles allow it. In the Magdeburg circle, the examination of meat has been obligatory since 1865, and in that of Cassel since 1871.

THE USE AND ABUSE OF THE GYMNASIUM.

Two severe accidents occurring during gymnastic exercises recorded in the hospital reports of one journal (the *Boston Medical Journal*), in one case proving fatal, suggest to it comments on the dangers attending the system on which gymnasia are usually conducted. It is rare, fortunately, that the faults of this system are made apparent by a melancholy accident such as this, but it is only in such cases that the public generally is warned that exercise in the gymnasium is not confined to moderate limits, but may mean work of a much more serious character. The weak and the strong alike are led step by step until the point of endurance has been passed by many, in a vain attempt to emulate feats which should be attempted only by the most powerful and skilled gymnasts. Indeed, some of the performances daily practised by many young men should be absolutely prohibited in the gymnasium. It is hardly necessary to say that great discrimination should be made in regard to the character of exercise suitable to each individual; and that is particularly true in the case of young men and boys, who are the most constant frequenters of the gymnasium. During the period of adolescence, injuries may be inflicted which will eventually break down the most powerful frames. Cases of this kind are common enough to the physician. The remedy is a simple one. Place the gymnasium under the control of a medical officer who shall be the sole judge of the exercise suitable for each individual. Exclude acrobatic performances altogether, and we shall hear less of strained hearts and weakened lungs, while severe injuries like those we have to-day to record will be unknown. This system of supervision has been fully tried at Amherst College, and has worked in the most satisfactory manner.

CASTS OF SKULLS.

PROFESSOR FLOWER, the conservator of the museum of the Royal College of Surgeons, reports that the collection contains a series of casts of the interior of the cranial cavity, representing exactly the form and size of the brain (when covered by its membranes) of men of various races and many other species of animals. With a view to diffuse the information to be derived from the study of these casts, and believing that many members of the profession and many educational institutions will be glad to avail themselves of the opportunity of possessing them, the Council of the College has authorised the issue of copies at the lowest cost at which they can be reproduced, which, of course, will partly depend upon the number likely to be required. The following is a list of casts of which duplicates can be obtained. The numbers prefixed to the names are marked on the casts; the numbers after the names refer to the specimen in the Osteological Series from which the cast was made: 1. Man (*European*), 5733; 2. Man (*Turk*), 5563A; 3. Man (*Tartar*), 5484 (remarkably brachycephalic); 4. Man (*Chinese*), 5489A; 5. Man (*New-Zealander*), 5389; 6. Man (*East African*), 5378A; 7. Man (*West African*), 5363B; 8. Man (*Bushman*), 5357; 9. Man (*Australian*), 5317 (Port Essington, compressed type); 10. Man (*Australian*), 5331 (Adelaide, depressed type); 11. Gorilla (*Troglodytes gorilla*), adult male, 5178; 12. Chimpanzee (*Troglodytes niger*), adult male, 5086; 13. Orang (*Simia satyrus*) adult male, 5054; 14. Siamang (*Hylobates syndactylus*), 5032; 15. Entellus Monkey (*Semnopithecus entellus*), 5006; 16. Macaque Monkey (*Macacus cynomolgus*), 5000; 17. Chacma Baboon (*Cynocephalus porcellus*), 4723; 18. Howling Monkey (*Myces seniculus*), 4718; 19. Squirrel Monkey (*Callithrix sciureus*), 4666; 20. Ruffed Lemur (*Lemur varius*), 4661; 21. Galopithecus volans, 4630B; 22. Tupaia (*Cladobates tana*) A 2398a; 23. Tenrec (*Centetes caudatus*), 2396B; 24. Hedgehog (*Erinaceus Europeanus*), 2392A; 25. Rousette Bat (*Pteropus edulis*), 2422A; 26. Tiger (*Felis tigris*); 27. Dog (*Canis familiaris*); 28. Walrus (*Trichechus rosmarus*), 3868; 29. Porpoise (*Phocena communis*), 2512A; 30. Dugong (*Halicorn dugong*), 2634; 31. Elephant (*Elephas Indicus*); 32. Hippopotamus (*Hippopotamus amphibius*); 33. Pig (*Sus scrofa*), 3263; 34. Ox (*Bos taurus*), 35. Camel (*Camelus Bactrianus*); 36. Horse (*Equus caballus*); 37. American Tapir (*Tapirus terrestris*); 38. Sumatran Rhinoceros (*Rhinoceros Sumatrensis*), 2938; 39. Hyrax (*Hyrax capensis*), 3115A; 40. Capybara (*Hydrochærus capybara*); 41. Beaver (*Castor Canadensis*), 2159; 42. Rabbit (*Lepus cuniculus*); 43. Sloth (*Cholepus didactylus*), 2387B; 44. *Glyptodon clavipes* (fossil), 417A; 45. Kangaroo (*Macropus giganteus*), 1732; 46. *Thylacoleo carnifex* (fossil), 1539A; 47. Wombat (*Phascogalemys wombatus*); 48. *Dasyurus ursinus*; 49. *Echidna hystrix*; 50. *Ornithorhynchus paradoxus*. Applications for any, or all, should be made to Professor Flower, at the College of Surgeons.

MANSLAUGHTER BY MIDWIVES.

REFERRING to the recent case at Coventry, which we lately noticed, in which a midwife has been committed by a coroner's jury for manslaughter, on the ground that she had neglected a warning not to attend lying-in women, lest she should infect them with puerperal fever, the editor of the *Obstetrical Journal* writes: "There are several points of interest in this case. First, the question as to the contagiousness of puerperal fever, the reality of which some individuals might perhaps be found to dispute; second, the legal right of a coroner to step in and warn an obstetrician not to attend women in labour; and thirdly, does not it again demonstrate the necessity of instructing midwives? Mrs. Ingram's attainments are sufficiently manifested in her answer to the

INFECTIOUS DISEASES IN FAMILIES.

THE following important notice has been issued by the authorities of the London Fever Hospital for public information. The London Fever Hospital assists in preventing the spread of contagious fever, and receives as patients working men and their families, domestic servants, clerks, and *employés* in commercial houses. It also provides special wards for private patients, where they may, if desired, be attended by the family medical attendant. The hospital was founded in 1802 for the treatment of patients suffering from contagious fever, and from that time up to the opening of the Metropolitan Fever-Asylums was the only institution of the kind in the metropolis. The Metropolitan Fever-Asylums having now relieved this hospital of the responsibility of taking charge of the very poor, the attention of the committee has been given to the prevention of the spread of contagious fever, by rendering the hospital available for the reception and treatment of cases of fever occurring in families in good circumstances, or in schools, hotels, among the *employés* of large commercial houses, etc., while continuing to offer its benefits to the working classes not receiving parish relief. The arrangements they have adopted for the present are as follow. 1. Working men or their families are admitted at once without payment and without letter of recommendation, on the production of a certificate from a medical man, stating that they are suffering from contagious fever, and are not in receipt of parish relief or otherwise proper cases for the Metropolitan Fever Asylums. 2. Domestic servants, *employés* in houses of business, and others similarly situated, who are sent to the hospital for the convenience of employers, will be admitted into the general wards on the recommendation of a governor or annual subscriber of one guinea, or as heretofore, on payment of two guineas on admission. 3. For such

patients as require isolation and better accommodation than that offered by the general wards, eight large rooms have been prepared and furnished with every requisite for comfort, in which a single patient, or two children of the same family or from the same school, can be received. The payment for one of these rooms, with the attendance of an experienced nurse, and the care of the resident medical officer and physicians, and including food and medicines, has been fixed at three guineas per week. If desired, cases admitted into the private wards may be attended by the family medical attendant. The committee are assured that, in making provision for private patients, they meet an urgent public requirement, and they are prepared to extend the accommodation should the demand for an extension arise. The hospital will, at the same time, continue to render public services of the highest value, by receiving working men and the members of their families, who might otherwise, through an attack of fever, be compelled to take the first step towards pauperism by seeking parish relief. In order that those who may need the accommodation offered by the hospital, when attacked by contagious fever, may be acquainted with the arrangements made for their reception, it is desirable that the existence of these arrangements should be made as generally known as possible, and the committee seek, for this purpose, the co-operation of all directly or indirectly interested in the public health. A carriage for the conveyance of fever-patients is kept at the hospital, and is sent at once for cases requiring admission, the only payment asked being for horse-hire.

THE AGE AT WHICH CHILD-BEARING CEASES.

A PAPER was recently read by Dr. Fordyce Barker before the New York Medical Library and Journal Association, upon "The Age of Women when the Capacity for Child-bearing Ceases". The object of the paper, as abstracted in the *Boston Medical Journal*, was to define physiologically, and as a matter of experience, what are the limits to the reproductive function of women. Ovulation and menstruation, though often coincident, do not necessarily bear to each other the relation of cause and effect, nor does ovulation always occur at the time of menstruation. Menstruation is, therefore, to be regarded as an accidental and incidental phenomenon, and is a flow of blood from the interior of the uterus at stated periods, irrespective of ovulation. Ovulation, but not menstruation, is essential to conception. The occurrence of menstruation in a woman advanced in years is no evidence of the occurrence of ovulation at the same time. When senile atrophy of the ovaries takes place, ovulation ceases and conception is no longer possible. Usually this period is reached between the fortieth and fiftieth years of the woman's age. In very exceptional cases, this change does not take place until from one to four years later. Dr. Barker alleges that these are well-established facts, proved by multitudes of *post mortem* examinations: and, moreover, that not a single authenticated case has been known of a woman over fifty-five years of age who has given birth to a child, except that of Sarah, the wife of Abraham. Many such have been reported, but none are supported by conclusive evidence: hence the conclusion that the laws of physiology, the experience of mankind, and the decisions of the courts will justify the medical witness in declaring, when questioned in court as to the age during which child-bearing is possible, that a woman over fifty-five years of age is past the period of child-bearing. In further proof of the fact that though menstruation and ovulation are generally coincident, they do

not bear the relation of cause and effect, Dr. Barker stated that the one may exist without the other, as proved by many well-established cases; that cicatrices have been found in ovaries, indicating rupture of Graafian vesicles, many years previous to the appearance of menstruation, and that fresh cicatrices have also been found in old women a long time after the cessation of menstruation; that we have now eight well-authenticated cases in which women have menstruated and continued to do so after both ovaries were removed, rendering ovulation impossible. In the discussion which followed the reading of the paper, Dr. Caro remarked that, during his residence in Sicily, the Government recognised the possibility of child-bearing commencing at the age of eleven years and two months, and continuing to the age of fifty-four or fifty-five years. He reported that while living there he had personal knowledge of a woman who had given birth to thirty-one children; and that twenty-two of them had sat at the same table. This woman gave birth to her last child when she was fifty-four years old. It was supposed she had a double uterus, from the fact that a child was born every *six months*. Unfortunately, when the woman died, no *post mortem* examination was obtained.

THE ROYAL BOTANICAL SOCIETY.

THE usual annual course of eight lectures on Botany by Professor Bentley will be delivered on Fridays, commencing May 14th, at the gardens of the Society in the Regent's Park. The admirable medical flower and herb garden which this Society possesses is insufficiently known to medical students and practitioners. There is nothing more instructive than the study of these living and growing specimens; and we particularly recommend Professor Bentley's early morning course of systematic botany, delivered at the gardens at 8 A.M. during the spring and summer months, to students of medical botany. The course is in its way unrivalled, and the early morning study in these delightful gardens is both physically and intellectually profitable. These lectures are largely attended by pharmaceutical students. There is no reason, we think, except that they are not sufficiently known, why they should not also attract a large class of medical students.

VIVISECTION.

A CORRESPONDENCE has been carried on in the columns of the *Times*, during the last week, on the subject of "Vivisection," between Mr. Hutton, the able editor of the *Spectator*, and Mr. Ernest Hart. The subject matter is, however, in no important way new to the majority of our readers; and, as the correspondence is long, we need not reproduce here any part of it. In the course of the correspondence, Lord Harrowby has intervened to announce that the Society for the Prevention of Cruelty to Animals is not responsible in any way for the statements of the memorial or for its promotion. Baroness Burdett Coutts pleads the cause of the humming-birds of Brazil, which are much used for the plumage of ladies' hats. We recommend to the Society's attention, the gelding, nicking and docking of horses; the repeated bleeding of calves; the cropping and snipping of dogs; the trimming of game-cocks in public exhibitions; the coursing of hares (especially in enclosures); the wholesale maiming and murdering of pigeons at Hurlingham; the pegging of lobsters; and the production of liver-disease, in its largest and most painful development, in geese. If the principle that pain, inflicted for purposes of sport, commerce, luxury, and convenience, be admitted by the Society—if it look with complacency on gelded horses, cropped dogs, castrated tom-cats, exhausted hares, maimed and half-murdered pigeons, emaciated and diseased geese, not to speak of tortures by the trapper and huntsman further afield—it is hard to understand the plea that the art and science which aims at saving human life, shall alone be prohibited from authority over the life of lower animals.

RECENT URBAN MORTALITY.

DURING last week, 5,909 births and 4,080 deaths were registered in London and twenty other large towns of the United Kingdom. The annual death-rate was 28; in Edinburgh, it was 29; Glasgow, 28; and Dublin, 39. In eighteen English towns, it ranged from 17 in Ports-

mouth, and 18 in Wolverhampton, to 30 in Oldham, Nottingham 31, Manchester 31, Liverpool 32, Birmingham 35, and Salford 35. Whooping-cough, small-pox, and scarlet fever were all fatally prevalent in Birmingham; and the deaths from scarlet fever and enteric fever excessive in Sheffield. In London, 2,567 births and 1,650 deaths were registered; the births exceeded the average by 128, whereas the deaths were 26 below the average. To the seven principal zymotic diseases, 171 deaths were referred; being 83 below the average. The deaths referred to diseases of the respiratory organs were 409, being 4 below the corrected average number of the week. In "outer London", the death-rate from all causes and from the seven principal zymotic diseases was 20.3 and 2.3 per 1,000 respectively, against 25.0 and 2.6 in "inner London". The mean temperature of the air at Greenwich was 43.2 deg., or 5.1 deg. above the average. Rain fell on four days during the week, to the amount of 1.25 inches.

SANITARY STATISTICS IN THE FAR WEST.

UNMISTAKABLE signs of sanitary progress and increasing interest in health-matters may be observed in all parts of the world; and, in the present day of constant and rapid intercommunication among nations, no part of the world is so remote that its sanitary condition can safely be regarded with selfish indifference. Vital statistics have received much attention in America, and the subject has there been handled with much ability and industry. In many respects, sanitary organisation has in many of the States been for some years more complete than in this country; and the health-reports have frequently been State papers of more than ephemeral interest and value, especially in Massachusetts. The report of Dr. Henry Gibbons, the health-officer of the city and county of San Francisco, for the year ending June 30th, 1874, deserves more than a passing notice, partly from its intrinsic merit, and partly from its evidence of the due appreciation of the importance of sanitary matters in this city of the Far West. The city possesses a Board of Health, consisting of the mayor (who is the *ex officio* president), and five physicians, with a clerk. In addition to the health-officer, there are a quarantine officer, a secretary, two health-inspectors, a market-inspector, and a messenger. Such is the sanitary staff of San Francisco, and the total annual cost of the health-department is less than £3,000. At the outset of his report, the health-officer confesses to considerable difficulty in estimating the population of his city, as, since the last census in 1870, great changes have taken place in many of the wards, and the rate of increase has varied to a remarkable extent. He urges the taking of a city census in 1875; and states that, by following the recent example of Providence city, and utilising the police force as "census marshals", the enumeration could be carried out at the cost of a few hundred, or, at most, a thousand dollars. In the calculation of his rates of mortality, Dr. Gibbons adopts 200,770 as the population of the city—an estimate derived from a recently issued City Directory. The estimates, however, of the numbers living under five years of age, and between five and seventeen years, are formed from numbers obtained at a recent school census. One of the most noticeable features in the city population is a colony of Chinese estimated at 14,500, who are stated to be liable to a considerably higher death-rate than the rest of the population. During the year to which the report relates, the rate of mortality in the city was equal to 20.3 per 1,000 of the estimated population, against 17.4 and 17.5 in the two preceding years. It appears, from a table showing the death-rates in fourteen of the largest American cities, that San Francisco is one of the healthiest in the States. The increased death-rate in the year 1873-4 was due to the epidemic prevalence of scarlatina, which caused a death-rate equal to 1.9 per 1,000 of the population. Among the Chinese, the rate of mortality from all causes was equal to 32.1 per 1,000, against 19 in the American population. It is difficult, however, without more definite information, to decide how far this is due to the effect of abnormal distribution of age. It appears that, of the Chinese, little more than 10 per cent. are aged under seventeen years; whereas, in the rest of the population, the proportion was more than 46 per cent.

If the Chinese population consist almost exclusively of adults past middle age, then the apparently high death-rate does not imply low sanitary condition; and this supposition is supported by the fact that, among the small number of Chinese under seventeen years of age, the mortality was at the rate of only 23.3 per 1,000, against 27.4 among the rest of the population under that age. In a city of such rapid growth as San Francisco, it is important, in order that its death-rate may be properly estimated, that the proportional distribution of ages of the population should be known and taken into account. Among children under five years of age, the death-rate in the city in 1873-4 was equal to 61.9 per 1,000, which was 3.8 per 1,000 lower than the English life-table rate at those ages, but exceeded by 22.5 per 1,000 the rate in the healthy districts of England. Should a census of the population be taken during the present year, it is to be hoped that Dr. Gibbons, in his next report, will still further prosecute his inquiry into the death-rate at the different groups of ages, and the proportional distribution of the population, especially at the later periods of life—say at the age of sixty years and upwards. Beyond all question, however, the death-rate in San Francisco is low, and the city may be called healthy by comparison with most other large cities, American and European; and this in spite of many nuisances and sanitary shortcomings, which are dwelt upon in the report in forcible language, which will doubtless command the attention from the Board of Health which it deserves. Washerwoman's Bay, Mission Bay, and Mission Creek, are especially condemned for their sanitary condition. With respect to Mission Creek, from its source past "its intersection with Harrison—the very recollection of which locality by a person who has visited it is almost sufficient to sicken—to the outlet in Mission Bay, and even beyond, it smells to Heaven with a loudness and persistence that the strongest nostrils may not withstand, and the disinfectants of a metropolis could not remove." When these and other described nuisances are abated, there appears to be nothing to prevent San Francisco from becoming one of the healthiest cities in the world. Climate and temperature are evidently in its favour. According to a table based upon the observations of twenty-four years, the mean temperature of January and December is 48.9 deg. and 50.3 deg., and it ranges in the other months only from 52.1 deg. in February to 61.8 deg. in August.

SCOTLAND.

THE death-rate in Glasgow was last week reduced to twenty-eight, the lowest it has been since October. The reduction is mainly in pulmonary complaints, and unclassified general ailments of organic origin.

A BAZAAR recently held in Edinburgh in behalf of a hospital for incurables realised the sum of £4,500, and a quantity of goods remain unsold. The Duchess of Edinburgh contributed £30, and a "well-wisher" £100.

THE following appointments have been made in the Glasgow Western Infirmary. *Physician*: Dr. James Finlayson; *Dispensary Physicians*: Dr. G. P. Tennent and Dr. Joseph Coats; *Extra Dispensary Physician*: Mr. D. C. McVail; *Pathologist*: Dr. Joseph Coats; *Surgeon*: Dr. A. Patterson; *Dispensary Surgeons*: Dr. J. G. Lyon and Dr. W. B. Fleming; *Extra Dispensary Surgeon*: Dr. David N. Knox.

IRELAND.

ON the recommendation of Colonel Peel Dawson, the lieutenant of the county, the Lord Chancellor has appointed Dr. James C. L. Carson and Dr. Robert Sharp, both of Coleraine, to be magistrates for the county of Londonderry.

ROYAL COLLEGE OF SURGEONS OF IRELAND.

DR. CROLY, jun., has been elected a member of Council of the Royal College of Surgeons, in the room of the late Dr. R. Adams; and Dr.

Croly, senior, has been appointed examiner in midwifery in the place of Dr. Cronyn, resigned. It was announced by mistake, in last week's JOURNAL, that Dr. Cronyn, lately appointed Professor of Midwifery to the Royal College of Surgeons, had resigned the professorship; it should have been stated that he resigned the examinership.

THE PROFESSORSHIP OF CHEMISTRY IN DUBLIN UNIVERSITY.

THE election to this professorship has been postponed for a week. The following are the candidates: Richard Apjohn, A.M.; Edmund Wm. Davy, A.M., M.D., M.R.I.A.; M. Forster Heddlé, M.D.; Henry King, A.M., M.B.; Dr. Emil König (Tubingen); John William Mallet, A.B., LL.D.; Temple Augustus Orme; James Emerson Reynolds, L.K.Q.C.P.L., F.Chem.S. London and Berlin; George F. Rodwell, F.R.A.S.

THE KING AND QUEEN'S COLLEGE OF PHYSICIANS: THE NEW CHARTER QUESTION.

WE learn from the Dublin newspapers, that Dr. Lyons brought forward his proposal for a meeting of the licentiates of the College, to consider the proposed supplemental charter. Dr. Lyons' motion, not having been seconded, fell through. Since our last number was published, a rejoinder to the College answer to the dissent has been forwarded to the Chief Secretary for Ireland, and has been ordered by the College to be printed as a supplement to the other papers printed and forwarded in the preceding week. The rejoinder brings forward no new point.

HOSPITAL SUNDAY AND THE DUBLIN EYE AND EAR INFIRMARY.

As noticed in our issue of last week, the Dublin Eye and Ear Infirmary was refused a grant from the Hospital Sunday Fund, on the ground of its being more of a private than a public institution. As might have been expected, the Surgeon-in-Chief—rather a grand title for a medical officer of a small special hospital—has written an indignant letter to the committee, and published it in the Dublin newspapers. The honorary secretary has answered the "chief surgeon's" letter, and, we think, finally disposed of the very special argument in favour of the very special institution. All the other participating hospitals seem satisfied, and certainly have shown no public sign of discontent.

THE KING AND QUEEN'S COLLEGE OF PHYSICIANS: THE NEW BUILDINGS.

THE new hall of the College of Physicians is now almost complete. This will be a valuable addition to the College. The hall has been built with the express object of accommodating large meetings of the medical and scientific societies which hold their meetings within the College walls. Few public medical corporations have taken so much trouble, and gone to such expense, as the Irish College of Physicians in providing space for the meetings of the profession.

ROFUNDU LYING-IN HOSPITAL.

THE annual report of Dr. Johnston, the master of this institution, the largest of the kind in Europe, has lately been published, and from it we find that there were 1236 deliveries during the year, and only 15 deaths from all causes, viz., placenta prævia, 1; apoplexy, 1; convulsions, 1; scarlatina, 3; bronchitis, 1; peritonitis, 3; pyæmia, 1; sloughing, 1; fatty degeneration of kidneys, liver, and heart, 1; typhus, 1; typhoid fever, 1. This mortality is extremely small, considering the epidemic of scarlatina, which has existed for so many months in Dublin, and also the prevalence of other zymotic affections; especially, also, when it is considered the class of people admitted, many having been seduced or deserted, or ill treated by their husbands, or whose husbands had died lately. The low death-rate is attributable by Dr. Johnston to the strict attention to cleanliness, and to the fact that there was a constant current of pure air permeating the wards, and rendering any poisonous emanations innocuous. Of the 1236 deliveries, in 997 the labour was perfectly natural, terminating within 24 hours, and in 40 it lasted over that period. In 45 cases, the ovum was expelled at the sixth month; and, in 138 cases, the forceps were

used, 105 of whom were primiparæ, of whom 5 died. There were 24 cases of twins, and version was performed 14 times. *Post partum* hæmorrhage occurred in 25 cases, and 104 women had chloroform administered without any bad result. The report is a satisfactory one; and, considering the number of inmates, the mortality is extremely low, and reflects great credit on Dr. Johnston's supervision of this institution.

DR. JAMESON OF DUBLIN.

THIS gentleman died at his residence in Harcourt Street, on last Monday, at the age of 72. He was for many years connected with Mercer's Hospital, as surgeon, but resigned some few years since. He was an ex-president of the Royal College of Surgeons, and consulting surgeon to the Coombe Lying-in Hospital. Among his contributions to medicine were papers on Oedema of the Glottis, Strangulated Femoral Hernia, and Ovarian Dropsy. His death arose, it is believed, from renal and vesical disease.

POOR-LAW MEDICAL OFFICERS IN BELFAST.

AT a meeting of the Belfast Dispensary Committee, held on February 1st, Dr. Arnold gave notice that he would move the following resolution at the next meeting: "That, in view of the facts disclosed in the reports of Mr. O'Brien, Inspector of the Local Government Board, and of our honorary secretary, now read, regarding the exceedingly arduous duties of the several medical officers and the amount of duty discharged by them, in the opinion of this committee, it is imperative that additional dispensary medical attendants be appointed for the Belfast Poor-law district." The *Belfast News-Letter*, in commenting on the proposal, justly remarks that, although at first sight the additional appointments may seem to increase the burden on the ratepayers, the increased medical care, by diminishing the amount of sickness and mortality, would really tend to diminish the taxation; and that, even if a trifling additional taxation were involved, it is a duty, in the interests of the poor and for the sake of humanity, to submit to it.

THE BIRTHS AND DEATHS IN DUBLIN DURING 1874.

DURING the year 1874, there were registered in the Dublin registration district 8,903 births, equal to a ratio of 28 per 1,000 of the population. The weekly average was 171. The deaths registered during the year were 8,190; equal to 26 in every 1,000 of the population, which was also the average death-rate for the previous ten years. The rate was equal to 28.6 in every 1,000 of the male population, and to 23.8 per 1,000 of the female population. The deaths registered in Belfast during the year afforded a ratio of 29 in every 1,000 persons living; in Cork, 24; in Limerick, 24; in Londonderry, 20; in Waterford, 25; in Galway, 21; in Sligo, 17. As many as 604 deaths from scarlet fever were registered in Belfast during the year, of which number 401 were registered in the last quarter. The deaths from zymotic diseases registered in Dublin exceeded the average of the preceding ten years by 63—the number being 1,916, or 1 in every 4.3 of the deaths, and 61 in every 10,000 persons living. Scarlet fever, which has been epidemic in Dublin for the last fifteen months, proved most fatal, causing 834, or 10 per cent., of the total deaths. The deaths due to fever were 352; to small-pox, 2; whooping-cough, 30; measles, 97; diarrhoea, 203; diphtheria, 41; croup, 113; quinsy, 19; and erysipelas, 49. Bronchitis caused 1,000 deaths; pneumonia, 206; heart-disease, 376; and phthisis, 862.

THE ARCTIC EXPEDITION. The following is, we believe, a correct list of those medical officers the names of whom have been submitted for approval to Mr. Ward Hunt for service with the new Arctic expedition, viz., Staff-Surgeon Colan, M.D., and Surgeon E. L. Moss, M.D. These two officers are intended to serve immediately with Captain Nares. Staff-Surgeon of the 2nd Class Belgrave Ninnis, M.D., and Surgeon R. M. Coppinger, M.D., will, no doubt, be attached to Commander Markham's ship. Dr. Colan has gained for himself a high reputation in connection with the successful cure of Sir J. E. Comberell's severe wound, received on the West Coast of Africa.

DR. RUMSEY, F.R.S.

At a meeting of the Council of the Gloucestershire Branch of the British Medical Association held at Gloucester, January 28th, after an expression of sympathy with the family of Dr. Rumsey, the following resolution was unanimously adopted; and the secretary was requested to send copies of the same to the editor of the *BRITISH MEDICAL JOURNAL*, and to the general secretary of the Association.

"That the Council of the Gloucestershire Branch having heard, with profound regret, of the serious illness of Dr. Rumsey, and of his consequent incapacity for further professional work, desire to call the attention of the executive of the Association, and of the members generally, to the many and valuable services rendered by Dr. Rumsey, during a period of more than thirty years, to the cause of public health. They would suggest that such services are entitled to public recognition, and would urge the Association to use its influence for the furtherance of this object."

EDINBURGH.

[FROM OUR OWN CORRESPONDENT.]

The New University Buildings.—Hospital Sunday.—Fever Accommodation in the New Infirmary.

LAST week, the acting committee who are looking after the New University buildings made their award among the plans of the four architects who competed. Their choice fell upon the designs of Mr. R. Anderson of Edinburgh. Mr. Anderson had taken great pains to make himself acquainted with the requirements of modern university buildings to be devoted to scientific purposes, and spent some time on the Continent examining into the arrangements of several of the principal universities of France and Germany. In the present designs, he has wisely made the internal arrangements the principal object of attention, and has subordinated the external appearance to them. In general terms, the various class-rooms and museums, with their appurtenances, are ranged round a central court of somewhat irregular shape, and take up rather more than three of its sides, the fourth side being appropriated to the Great College Hall. This last, which is situated on the east side of the building, is designed in the form of a Greek theatre, and is capable of holding from 2,000 to at most 2,500 persons, its floor being on a level with the first floor of the other buildings. The anatomy class-room, lying on the south side, is circular in form, with a diameter of 55 feet, and intended to hold 400 students. Near it, on the top storey, is the dissecting-room—an arrangement similar to the one which is in use at present in the University. Connected with it are a bone-room, a microscopic-room, and other smaller apartments for injecting, etc. In the same part of the buildings, namely, the south side, are situated the class-rooms for surgery and practice of physic, each to hold 250 students. In the front of the south side lies the great museum, measuring 112 feet by 40 feet, and entirely lighted from the roof. On the west side, adjoining the New Infirmary, are the chemistry-rooms, including class-room, laboratories, practical department, and workshops, all of the most ample description, the class-room being large enough to accommodate 400. Near it are the midwifery and pathology departments, one above the other. On the north side lies the principal entrance, into Heriot Row, several large reading-rooms for professors and students are placed, together with other rooms in connection with the College Hall. At the east end of this front come the materia medica and medical jurisprudence departments, and beyond them the great hall. The style of architecture adopted is the *cinquecento*—a phase of Italian, and one which, while it gives ample scope for satisfactory internal arrangements, is characterised externally by a look of solidity and dignity which is very suitable to its object. The central part of the side facing the street has three storeys above the basement, the remainder of the building only two. From within, the central court, the great hall, and the museum are striking and conspicuous objects. At the north-west corner of the great hall, a campanile, rising to the height of 230 feet, is placed, which serves two purposes—the one that of a belfry, the other as a ventilator to the great hall, as two ventilating shafts pass up along the tower. The architect estimates that the building, without the tower just spoken of, should be erected for about £70,000, the sum fixed as a desirable limit to expenditure.

A further list has been published of Church Subscriptions received

on Hospital Sunday of about £150, making the sum total nearly £1,800.

The town authorities and the Infirmary managers have at length come to terms regarding the debated points of fever accommodation in the new infirmary. There is to be accommodation always for fifty fever patients, and, in case of an epidemic, three small outbuildings which stand apart from the principal buildings will be brought into requisition, thus giving thirty additional beds. The equally debated question of what we are to do with the sewage of the new hospital still remains unsettled, as some of the town-councillors persist in thinking that the passage of infirmary sewage through the ordinary drains will be likely to injure the health of the inhabitants, in spite of Sir Robert Christison's assurances to the contrary. The great advantage of the route proposed by the managers was clearly shown, inasmuch as by the St. Leonard's route the fall is 1 in 141, while that to the westward is only 2 in 227, sometimes as little as 1 in 438.

ASSOCIATION INTELLIGENCE.

BIRMINGHAM AND MIDLAND COUNTIES BRANCH.

The next meeting will be held in the Council Room of the Midland Institute, on Thursday, February 11th, 1875. The Chair will be taken at three o'clock P.M. precisely.

Business.—To receive a Report from the Habitual Drunkards Committee.

Notice of Motion.—Dr. Fowler Bodington will move: "That the amended Report of the Education Committee, together with the scheme, be adopted by the Branch, and forwarded to the Editor of the *JOURNAL* for publication."

Papers.—1. On Functional Derangements of the Ovaries. By Dr. Malins.

2. Remarks on the Treatment of Skin-Diseases at General and Special Hospitals. By Dr. Mackey.

3. On Rheumatic Hyperpyrexia. By Mr. F. E. Manby.

Members are invited to exhibit Pathological Specimens at the commencement of the meeting.

BALTHAZAR FOSTER, M.D., } *Honorary Secretaries.*
JAMES SAWYER, M.D., }

Birmingham, February 1875.

NORTH WALES BRANCH.

The intermediate meeting of this Branch will be held at the Castle Hotel, Conway, on Tuesday, February 16th, at 12.30 P.M.; THOS. E. JONES, Esq., President, in the Chair.

Dinner at 3.30 P.M.

T. EYTON JONES, *Honorary Secretary, pro tem.*

Wrexham, January 19th, 1875.

BATH AND BRISTOL BRANCH.

The fourth ordinary meeting of this Branch will be held at the York House, Bath, on Thursday, February 18th, at 7.15 P.M.; F. MASON, Esq., President.

R. S. FOWLER, } *Honorary Secretaries.*
E. C. BOARD, }

Bath, February 1st, 1875.

SOUTHERN BRANCH: EAST DORSET DISTRICT.

A GENERAL meeting of this District will be held at the London Hotel, Poole, on Thursday, February 18th, at 1.30 P.M.; H. D. ELLIS, Esq., President, in the Chair.

Business.—1. To promote combined action with the Bournemouth and West Dorset Districts.

2. To elect officers for the present year.

3. To appoint the number, places, and times of meetings during the year, and the amount of annual subscription.

Dinner at 4 P.M., at the London Hotel; charge, 5s., exclusive of wine.

C. H. WAITS PARKINSON, *Hon. Sec.*

Wimborne, January 31st, 1875.

METROPOLITAN COUNTIES BRANCH.

An ordinary meeting of this Branch will be held at the rooms of the Medical Society of London, 11, Chandos Street, Cavendish Square, on Friday, February 19th, at 8 P.M., when Dr. Lockhart Clarke, F.R.S., will read a paper on Cases of Paralysis.

ALEXANDER HENRY, } *Hon. Secretaries.*
ROBERT FARQUHARSON, }

February 1st, 1875.

BATH AND BRISTOL BRANCH: ORDINARY MEETING.

THE third ordinary meeting of the Branch was held at the Royal Hotel, Bristol, on Thursday evening, January 14th; F. MASON, Esq., President, in the Chair. There were also present thirty-four members and one visitor.

New Member.—E. S. Greensill, Esq., Royal United Hospital, Bath, was unanimously elected a member of the Association and this Branch.

Papers.—The following papers were read.

1. On Failures of our Art. By T. Cole, M.D. This led to an animated discussion, in which Drs. Inman, Bellloc, Shingleton Smith, and Messrs. Collins, Tibbits, and Bartrum, took part.

2. The Classification of Cases of Blood-Poisoning. By R. W. Tibbits, M.B. After a few remarks from Dr. Dobson, the further discussion of this important subject was deferred until the next meeting.

SOUTH OF IRELAND BRANCH: ORDINARY MEETING.

THE third meeting of the session 1874-75 was held in the theatre of the Royal Cork Institution, on Wednesday, January 13th; Dr. THOMAS GREGG, President, in the chair.

Arterio-Capillary Fibrosis.—Dr. RINGROSE ATKINS read a paper on this subject. Having first described the minute anatomy of granular contracted kidney, he detailed the views of Sir William Gull and Dr. Sutton on this so-called pathological condition, and then discussed a series of experiments and observations made by him, the result of which supported Dr. George Johnson's views on this subject. The conclusions arrived at from these experiments were as follows. 1. Glycerine alone will generally (though not in all cases) produce the so-called "hyaline-fibroid" appearances of the walls of the arterioles in specimens set up in it. 2. A mixture of equal parts of glycerine and camphor-water will invariably produce these appearances, corresponding almost exactly to those described by Gull and Sutton as being due to morbid processes. 3. The maximum distension and consequent "hyaline" appearance of the outer elastic coat of the arterioles is produced by the glycerine and camphor-water solution acidified. He next examined, on pathological grounds, the tenability of the above-mentioned authors' views, pointing out many facts brought forward by them in support of their doctrine, which could be equally well explained on other grounds; then, adverting at some length to the views of Johnson, Traube, and Hamburger on the muscular hypertrophy of the walls of the arterioles found in chronic Bright's disease, he exhibited a specimen of an arteriole of the skin mounted in glycerine, where the hypertrophied muscular tissue was coexistent with the distended elastic outer coat, and concluded by hoping that each individual member, as opportunities presented themselves, would inquire into the vexed question for themselves, withdrawn though it may be from the beaten path of medical literature. The paper was illustrated with numerous microscopical specimens and drawings.

Therapeutic Uses of Electricity.—Dr. W. H. SANDHAM read a paper on electricity as a therapeutical agent, and illustrated his remarks by some interesting cases, in which this remedy was resorted to with complete success, and which had resisted other modes of treatment.

Injection of Perchloride of Iron in Post Partum Hemorrhage.—Dr. CURTIS gave the details of a case of injection of perchloride of iron in post partum hemorrhage, occurring in an extremely anæmic and enfeebled woman, who had already borne several children, and who was situated amidst the worst surroundings of overcrowding, and was badly nourished. The hemorrhage came on suddenly on the ninth day; and, on his being called to see the case, he found her quite blanched and almost pulseless; there was complete subinvolution of the uterus, which was yet quite soft and flaccid, easily admitting the fingers into its interior. Ergot had no effect, and the woman was dying of general profuse coining, some clots also passing away. On examination, with the assistance of Dr. S. O'Sullivan, he determined to inject perchloride of iron, which he did in the usual strength (one to three) to the amount of about four ounces. The effect was instantaneous; the bleeding was arrested; and finally, by the aid of good support, the patient made a good recovery.—A long discussion followed on the prudence of using the perchloride as a *dernier resort* in such cases. The general expression was in its favour, but only when other means had failed.—Dr. JONES detailed a case in which he had injected ergotine cutaneously under similar circumstances, with the best effect.—Dr. SANDHAM instanced a case where he had induced contraction *in extremis* by means of electricity, and spoke most strongly of this means of treating hemorrhage.—The PRESIDENT, after a long experience in midwifery, was glad to be able to recommend the old plans of checking hemorrhage which had always been adopted, cold in its various modes of appliance, ergot, pressure, and the cautious administration of stimulants. He

would not hesitate to inject perchloride, which he looked on as an invaluable resort in extreme cases. He was with the old authorities of the Dublin school, who deprecated the too free use of the hand in the uterine cavity. It should be remembered that the occurrence of such cases was very rare, and that the tendency to exalt these extraordinary aids would incline students and young practitioners, perhaps, to place less importance on the judicious management of their cases in regard to the due precautions to prevent hemorrhage during labour, and the control of such by means within the reach of all. No one, however, would underrate the value which the perchloride and transfusion conferred on obstetric practice.

CORRESPONDENCE.

HOSPITAL ABUSES.

SIR,—Permit me to invite the attention of the Association to the subject of hospital abuse; and to suggest that it take up in its corporate capacity the consideration of the best means of treating this gigantic evil.

I believe it could render no greater benefit to the public, as well as to our profession, than by employing its influence in the suppression of this prevailing perversion of charity; and I feel assured that no mere individual effort is equal to this purpose. Much has been attempted from time to time, yea, much has been done, both by individual as well as by combined exertions, and I gladly avail myself of the opportunity of bearing testimony to the fact; but I maintain that the difficulties are too great to be overcome by sporadic effort, and can only be adequately attacked by systematic and united action, such as the Association could afford.

I need scarcely adduce further argument in proof of the existence of this abuse of hospitals—it is admitted on all sides that hospital relief is misapplied to an immense extent; but I may be permitted to state that, through the vigilance of the lay-officers of the Royal London Ophthalmic Hospital, between five hundred and six hundred persons were refused admission as ineligible in one year.

And, if one hospital afford such facts, what must be the magnitude of the abuse which all those of the metropolis, as well as provincial ones, could furnish!

There is, indeed, no doubt that multitudes avail themselves of advantages too freely offered, and thus rob suitable recipients of the benefits provided by the benevolence of the charitable for the sick poor.

But, as medical men, giving our gratuitous services to hospitals, we should be very quixotic and unjust to ourselves were we silently to allow ourselves to be defrauded of our means of subsistence through the meanness of those who, under the guise of assumed poverty, obtain our unrequited help. It, therefore, becomes us to demand that all reasonable care be exercised to exclude from hospitals those whose circumstances enable them to obtain advice on the usual terms; and to this end, I invite the aid of the Association in devising a scheme for the suppression of this abuse, and moral influence in enforcing its adoption.

I am, Sir, your obedient servant,

J. C. WORDSWORTH, F.R.C.S.

London, 1st February, 1875.

DIPSOMANIA.

SIR,—It is now more than twelve months since I was urgently entreated by a former patient to try to establish a Home in the environs of London for the treatment of intemperance in the upper and middle classes. I therefore set myself the task of ascertaining whether such an institution would be desirable, whether it would receive the countenance and aid of my medical brethren, and whether it could be made self-supporting. On all these points, the evidence was conclusive, and in the affirmative.

That an institution devoted exclusively to this class of patients, and this only, was desirable, seemed proved by the fact, within my own knowledge, that many dipsomaniacs of the above classes, who would gladly avail themselves of such a Home did one exist, are now disposed

of either as inmates of lunatic asylums or of hydropathic establishments, or in the families of medical men or of clergymen, in none of which can they be treated as their case demands. The desirability was also attested by all those leading physicians and psychologists to whom I applied for information and advice on the subject, and who have kindly attached their names to the document accompanying this letter (see below). Further testimony was met with in the Report of the Select Committee on Habitual Drunkards. Dr. Forbes Winslow, in his evidence, expresses his belief that "if establishments were organised for the reception of persons addicted to chronic habits of intemperance, hundreds would avail themselves of these institutions, and voluntarily surrender themselves for a time to control and treatment. Such institutions are, to my mind, one of the great and crying wants of the age". Dr. Druitt expressed his opinion that inebriate asylums were quite as much required as lunatic asylums, and that "they would be the salvation of many".

That the Home I propose to establish would receive the countenance and aid of my professional brethren, I have every reason to believe, from the letters I have received from members of the profession in different parts of the country, and from the promised support of those eminent men who have signed the accompanying letter.

I am aware that many take a less sanguine view than myself of the amount of good likely to be achieved, and consider it essential that there should be a legal power of detention; and it is well known that the late Mr. Donald Dalrymple gave up his practice and entered Parliament for the express purpose of inducing the legislature to grant this power. Admitting the desirability of getting such a law passed, and the increased success in treatment that would result, yet I maintain, both from personal experience and from the reports I have received of the working of similar institutions in America, that much more might be done than is actually accomplished, were a more systematic method of treatment pursued than has hitherto been attempted in this country. This brings me to the last point of my inquiry—Whether the institution could be made self-supporting? On this subject, I have ascertained that, provided the establishment be conducted on a sufficiently large scale, little or no risk will be incurred. To assist me in raising funds for the purpose, the Earl of Shaftesbury has kindly promised to preside at a meeting to be held in Willis's Rooms at three o'clock on Thursday, February 11th; and I earnestly entreat all those of my medical brethren who are interested in the subject to come and support his lordship. Several eminent members of the three learned professions have promised to take part in the proceedings.

I am, etc., CARSTEN HOLTHOUSE.

George Street, Hanover Square, February 1st, 1875.

The following is the document above referred to:—"To Carsten Holthouse, Esq., 3, George Street, Hanover Square.—We, the undersigned, fully alive to the prevalence of this disease, and to the great want of an institution specially devoted to its treatment, are of opinion that such an one as you propose, which shall afford to its inmates the comforts of a home and the pleasures of society, while at the same time they are protected from temptation, would be a great boon both to the patients and to their families, and is well entitled to our recommendation and support.

"George Burrows, M.D., F.R.S. (*President of the Royal College of Physicians*); Thomas Watson, M.D., F.R.S.; Charles J. B. Williams, M.D., F.R.S. (*President of the Royal Medical and Surgical Society*); William Jenner, M.D., F.R.S.; William W. Gull, M.D., F.R.S.; J. Russell Reynolds, M.D., F.R.S.; C. B. Radcliffe, M.D.; Henry Monro, M.D.; William Wood, M.D.; H. Maudsley, M.D.; G. Fielding Blandford, M.D.; William Fergusson, F.R.S.; James Paget, F.R.S.; Prescott Hewett; Henry Thompson."

CRUELTY TO ANIMALS.

SIR,—The honourable and practical manner in which the Committee of Council has expressed its opinion on the recent so-called vivisection prosecution renders it needless for me to say much on that subject. I am sure that the action of the Committee of Council will gratify all those members who were present at, and voted for the continuance of, Dr. Magnan's experiments at Norwich.

As one who voted for the continuance of Dr. Magnan's experiments, you will, perhaps, permit me to make a few remarks on the general action of the "Society for the Prevention of Cruelty to Animals". I give in to no one in my admiration of the principles of that Society as expressed by its title, but I am compelled to take exception to the Society's mode of carrying out such principles. When one sees the amount of suffering that is inflicted every day on the lower animals,

suffering inflicted in our public streets, as Dr. Copeman pointed out before the magistrates at Norwich, inflicted often on account of fashion, and still no action taken by the Society, one cannot but for a moment imagine that we have travelled back to the dark ages, when, to be a man of science, was a surety of being prosecuted by those who thought they possessed a finer feeling of humanity than their fellows. This will, I think, be strengthened by reading some of the statements of the recent deputation on the subject. Those who heard Sir James Paget's calm but forcible reasoning on the justifiability, or not, of the infliction of pain on the lower animals (which was repeated by Mr. Cadge at Norwich), must have been struck by the contrast between Sir James's temperate remarks and those of some who denounced Dr. Magnan's experiments.

The subject has been so much misrepresented that, as you remark, nothing but free ventilation in the legislature will allay the public anxiety which has been called forth.

In addition to the forcible instances of cruelty to animals which you give in your article in last week's JOURNAL, permit me to jot down the following.

1. There is the one of the bearing-rein, which has been so much condemned in the daily press of late.
2. The practice of nicking and docking horses' tails, which is continually done. These operations are done to the manifest improvement of the appearance and carriage of the horse: still they cause pain, and are done to please fashion.
3. The practice of rounding foxhounds' ears, which means cutting off a considerable amount of the ears, so as to make the pack look uniform and light; it is, I am told, done in most kennels.
4. The practice of dubbing gamecocks. This consists of removing the skin and wattles from the throat, cheeks, and face of the birds, and the large comb on the head. This leaves a large surface which has to cicatrize. I am informed that no gamecock is exhibited without having been "dubbed". Now, as cock-fighting is not permitted, surely this must be a most unnecessary act of cruelty, and is simply done at the behests of fashion.

Yours obediently,

Fishguard, February 2nd, 1875.

J. HANCOCKE WATHEN.

YELLOW FEVER.

SIR,—In your *fréris* of the proceedings at the meeting of the Royal Medical and Chirurgical Society, on the 12th instant, I am reported to have said, that "I believed in no specific yellow fever, apart from malarious fever". May I ask you to be good enough to correct an error, the result, I imagine of my having been imperfectly heard? What I did say was, briefly, as follows—"I do believe in a specific form of contagious continued fever prevailing, within certain geographical limits, epidemically, and recurrent in formidable and destructive visitations at uncertain intervals, liable to be conveyed even beyond the latitudes within which it is most prevalent; altogether distinct and apart from malarious remittent, which occurs in the same localities, and is often seen in India, especially in the vicinity of the submontane regions, known as the Terai, where the conditions favourable to the development of malarial poisoning exist in abundance; and which, though it may be accompanied by yellow skin, brown dry tongue, delirium and stupor, hemorrhage from stomach and bowels, and even albuminuria, is not identical with the yellow fever of the West Indies, or such as the *Eclair* conveyed to Boa Vista and England, or such as I should have ventured to think, had I not been informed otherwise, was that which visited H.M.S. *Doris*, and which disappeared when she passed into other latitudes. This yellow fever, I remarked, was, as far as I knew, unknown in India, and that it is a curious fact such should be the case, seeing that the physical conditions usually supposed to be essential to its occurrence, exist in part of that country. But I mentioned the fact that fevers have occurred in India at different times, and in various places, such as the Mahamurree in Rohilkund, the Pali disease, the Burdwan fever, even now prevailing, that have been regarded as contagious, and, indeed, in some degree, may have become so, from intensity of insanitation and over-crowding; though it is probable that they are but forms of malarious poisoning, not to be grouped in the class to which yellow fever, typhus, etc., belong. However nearly certain forms of remittent non-contagious malarious fevers may resemble the real yellow fever, I think they must be regarded as quite distinct; and the distinction is of importance, not only in its pathological aspect, but also in regard to questions of quarantine. I also made a passing allusion to albuminuria as a complication of malarious as well as of real yellow fever, and that it was more frequently present than is sometimes suspected, and said that it is a question which merits further investigation.—I am truly,

J. FAYLER.

London, January 25th, 1875.

MALARIOUS FEVERS.

SIR,—As I have had some years of personal experience of malarious fevers in malarious districts, perhaps my facts may weigh somewhat against Dr. Inman's opinions. I do not think I misrepresent him when I say that he considers the cause of malarious fevers to be a great variation of temperature, notably between that of day and night; often due to the precipitation of the moisture which takes place after sundown.

1. In my experience, the time of the year during which the greatest variation of temperature occurred was the cold weather, December and January, when there was often a difference of 40 deg. Fahr. in the shade between day and night; but, at this time of the year, there was no fever except among those previously infected. At that time of the year, very heavy dews did occur; but, strangely, they did not produce fever.

2. The most sickly time of the year was not when the water covered the land, but in autumn, when it was drying up, and the surface of the earth was exposed, covered with putrefying vegetation. On the Brahmapootra, when the nights are cool comparatively, no one gets fever when sleeping in mid-stream, but, if the steamer be anchored in shore when the nights are very hot, then the fever seizes its victims; but, surely, if Dr. Inman and Dr. Oldham be right, the fever should be most apt to occur in mid-stream.

3. It is a notorious fact that new clearances, as in the tea-districts, are more unhealthy, not only for natives, but for Europeans who do not work in the sun. Old stations, kept free from shingle, with a river frontage not shut in by hills, remain free from fever, although in the centre of malarious districts, except in very wet seasons when the water drying leaves long growths of vegetation to putrefy in the sun.

4. In this country, many workpeople are exposed to greater variations of temperature than there are in India, but they do not get malarious fever.

5. I do not understand Dr. Inman's dogmatic assertion, that terrestrial emanations only take place by day. After sundown, in the tropics, the earth begins to radiate its heat, warming the lower stratum of the atmosphere, which rises and carries with it anything light enough to float in the current. Surely this is what is meant by a terrestrial emanation.

6. Everyone willingly admits the importance of all Dr. Inman says about prevention. The importance of a chill is generally admitted by both lay and medical residents in malarial districts; and to the recognition of this fact we must attribute the change which has taken place in Anglo-Indian dress—from cottons to flannels and tweeds; but he must not exalt an occasioning cause into the true cause of the disease.

The theory that decomposing vegetation forms a suitable nidus for the development of the poison of malarious fever seems to me to agree with all our knowledge, though, like the analogous theory of the cause of typhoid fever, it does not exclude other modes of development which are not perhaps so obvious.—I am, sir, your obedient servant,
Edinburgh, January 5th, 1875.

M. B.

CLUB PAYMENTS.

SIR,—Allow me—a practitioner of forty years' standing—to express my entire concurrence with your remarks on the subject of payments, etc., by clubs.

I have long striven, and not altogether unsuccessfully, in endeavouring to raise the rate of remuneration paid by Friendly Societies; and I was delighted to find that the medical men of North Wilts had unanimously resolved to increase the payments, and to fix a minimum. Whenever I have complained of the low rate of payment, I have been met by the remark: "It is all your own fault; the matter lays entirely with the profession; if you insist on a higher rate, we should be obliged to pay it; but, if one of you will not take the rate, others will," etc. And here lies the truth: we are not true to ourselves or to each other. It is the old old story.

I was glad, therefore, to learn that the men of North Wilts had roused themselves from their lethargy, and had determined to acquit themselves like men. I hoped their example would be followed in South Wilts and the adjoining counties; but to my disgust I read in the *Salisbury and Winchester Journal* of Saturday last the following.

"Trowbridge.—The several benefit clubs have been all up in arms about the contemplated advance in fees intimated by the medical men of North Wilts. A large and enthusiastic meeting has been held here, at which all the clubs have been pretty well represented, to confer with medical men of Trowbridge on the subject. The result has been, that the meeting was decidedly against the proposed change, and the new scale of fees has been entirely abandoned, as far as Trowbridge is concerned."

This is all I know of the matter; but it would be interesting to know

the why and wherefore of such a sudden change in the unanimous determination of the previous week.

Will some Trowbridge practitioner be so good as to enlighten the profession in the matter?

Your obedient servant,

L. OWEN FOX, M.D., F.R.C.S.

Broughton, Winchester, January 18th, 1875.

MEDICAL ADVERTISING AND MEDICAL REVIEWING.

SIR,—As I read in your pages the report of Mr. Lane's manly address at the Harveian Society, I was reminded of the following legend of the early Northmen. I quote from memory. "Denmark was overmatched by enemies; one especially of her heroes, with intelligent method, tried to stem the opposing force; he was outvoted, and retired to a cave in 'living death'. Time passed; the country's calamities increased; an oracle declared that the only salvation for the country was in resuscitating the rejected councillor; yet, it added, death would ensue to the intrepid one who broke into the cave. At last, a fearless and patriotic citizen dared the assault; dark mists and thunder followed the brave entry; for an instant, when the cloud cleared off, the aged sage was seen with beard grown through the stone table on which his elbows had rested for years; on the ingress of light and air, he revived, the table crumbled to pieces, and he exultingly exclaimed, 'It is well there are yet men in Denmark'. Animated by this augury, men took heart, worked, Denmark was saved." May I not compare Mr. Lane to the patriotic one who braved the threatened danger, and "dared to be free"? Let me commend the perusal of Mr. Lane's address to all who may not have read it, or have but slightly considered its important bearing.

Circumstances caused me to be detained on a wet Sunday, two years ago, at an inn in a county town. I was much thinking of the loose degrading system of medical authors' advertisements, especially in non-medical papers, quasi—"puffs". Two lines would return to my recollection:

"Pigmies are pigmies still, though perched on Alps;
And pyramids are pyramids in vales."

The inn's best room had but two books—a big Bible and a beautifully illustrated edition of *Don Quixote*. From the preface of the latter (the biography of Cervantes), I extracted the following, so much then in accordance with my train of thought; it will agree well with what was ably expressed by Mr. Lane, as told through your last number.

"Everything we know of the personal character of Cervantes adds to our appreciation of his writings. He was an accomplished scholar, a brave soldier, a kindly gentleman, and sincere and pious Christian. He was, as M. Viardot remarks, an illustrious man before he became an illustrious writer, one who was the doer of great deeds before he produced an immortal book."

I am, Sir, yours faithfully,

Hampstead, January 18th, 1875.

CHARLES F. J. LORD.

REPORT OF THE COMMISSIONERS IN LUNACY.

SIR,—I think most men holding public appointments in asylums will agree with the opinion expressed in your article on the report of the Lunacy Commissioners, on the 9th instant, that these gentlemen perform their duties in a courteous way, and with an evident desire to improve the places they inspect; but I demur to the conclusion your reviewer draws as to the "unmurmuring way in which their policy is everywhere received and acted upon". As a matter of fact, it is not so. There exists a chronic antagonism between the "great unpaid" and the commissioners, which mars the improvements and efficiency of many public asylums. For instance, at the Cambridge Asylum, the Commissioners have for seven years past urged the appointment of an assistant medical officer, and have even invoked the aid of the Home Secretary to remonstrate with the justices; but all in vain, though there are nearly three hundred patients here. Moreover, though they reported, in 1871, to the Home Secretary, that the same asylum was "inadequate and unfit", it remains in the same state, in spite of plans and correspondence. The history of the Kent and Middlesex Asylums is one long battle between the justices and their "enemies" at Whitehall. These things are not so apparent in the Blue Book, which has been reviewed through rose-coloured spectacles in the *JOURNAL*. For my part, I wish there were a simple despotism at Whitehall, and that the Commissioners were omnipotent. The asylums would be more satisfactorily managed, and there would be more encouragement to those who now waste their lives in doing good to an ungrateful and ignorant public in spite of itself.—I am, yours, etc.,

G. M. BACON, M.D., Medical Superintendent.

Cambridge co. Asylum, January, 1875.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

GOVERNMENT INQUIRY AT OVER-DARWEN.

WE have before us a local paper, in which there is a long account of the inquiry at Darwen, to which we called attention in our issue of January 23rd, as having been ordered to be held.

In consequence of a representation made by some of the inhabitants at Darwen to the Local Government Board, setting forth that the Darwen Local Board neglected its duty in the matters of drainage and the removal of refuse and other nuisances, and that, on account of these defaults, the health of the inhabitants of Over-Darwen had been endangered, a Commission, consisting of Lieutenant-Colonel Cox and Mr. Basil Cane, was appointed to inquire into the matter. Two of the petitioners appeared to prove the case. One of them, Mr. Deakin, read a long statement as to the general sanitary state of Over-Darwen, pointing out how many streets were without sewers; how nuisances very generally existed, and the want of paving, flagging, and channeling; how, in one place, the sewage ran from houses over the adjacent ground, finding its way ultimately through a brook into a mill-pond; how, in another street, the sewage from the houses ran into the River Darwen; how complaint was made as to the bad state of this street, in a letter which was read at the Highway Committee in January 1873, but "was then refused attention"; and so on. In the course of the proceedings, Lieutenant-Colonel Cox expressed the opinion that the allegation that the Local Board had failed in its duty as the Nuisance Authority could not be supported by saying that there were "nuisances in the streets, because that did not establish that there had been a failure in carrying out the Nuisance Removal Act". He added, that it was necessary to the carrying out of the Nuisance Removal Acts, that notice should be given to the Local Authority by certain persons only, enumerated in the Act 13 and 19 Vict., cap. 121; and that, "when a nuisance is found to exist, the Nuisance Authority shall cause complaint thereof to be made to a Justice of the Peace in order to establish a specific fault, and in order to abate the nuisance". He then added, "In enforcing that obligation, it will be necessary to show that the persons entitled to complain did complain, and that the Board had failed to do that of which complaint had been made." It thus appears to have been the fixed idea of the Commissioners, that no neglect could be imputed to the Local Board as regards the Nuisances Removal Acts, unless the Board's attention had been specially called to a certain nuisance by certain supposed qualified persons, and those only. Mr. Cane, the other Commissioner, also made remarks of a similar tenour to those of his colleague. This ruling of the Commissioners appears to us to be entirely wrong, and contrary to the law. Up to the passing of the Sanitary Acts of 1866, such an exposition of the law might have been correct; but, on the passing of that Act, it was altered. Part II of the Sanitary Act of 1866 is stated to be an "amendment of the Nuisances Removal Acts", and embraces the following return:—"It shall be the duty of the Nuisance Authority, to make, from time to time, either by itself or its officers, inspection of the district, with a view to ascertain what nuisances exist calling for abatement under the powers of the Nuisance Removal Acts, and to enforce the provisions of the said Acts in order to cause the abatement thereof, also to enforce the provisions of any Act that may be in force within its district, requiring fireplaces and furnaces to consume their own smoke."

With this section of an Act of Parliament in force, we fail to see how such a course of proceeding as that ruled to be adopted at the Darwen inquiry with reference to the Local Board's "default in enforcing the provisions of the Nuisances Removal Acts", can be sustained; and the only conclusion at which we can arrive on reading the report of the first day's proceedings is, that the Commissioners were in ignorance of the existence of the section which we quote above. It would seem that the General Inspectors have not even yet become acquainted with all their duties. Such proceedings as that of the first day of the Darwen Inquiry are not likely to induce gentlemen to complain of defaulting Local Authorities; and the public have a right to demand that inspectors sent down to investigate judicially such neglect as has for years obtained, shall be thoroughly acquainted with the Acts of Parliament under which they hold inquiry. We trust that Mr. Selater-Booth will, for his own credit's sake, himself see into this matter; for the Darwen Inquiry is (as his Inspector in his opening address said) one, the circumstances of which "are well known, not only in Over-Darwen and the Blackburn Union, but in the county, and far beyond the county".

POOR-LAW MEDICAL APPOINTMENTS.

BATE, George, M.R.C.S.Eng., appointed Assistant Medical Officer to the new Woolwich Union Infirmary at Plumstead, and Dispenser to the out-door poor, Plumstead District.
BUCHAN, Charles F., M.B., appointed Medical Officer and Public Vaccinator for the Ludham District of the Smallburgh Union, Norfolk, *vice* S. T. Huke, M.R.C.S.Eng., resigned.
BUCK, Joseph K., L.R.C.P.Ed., appointed Medical Officer for No. 1 District of the Worcester Union.
CRAVEN, John, L.R.C.P.Ed., appointed Medical Officer for the Parish of Thurso, Caithness-shire, *vice* W. Bruce, M.D., deceased.
DAKEYNE, Thomas E., L.R.C.P.Ed., appointed Medical Officer of the Leek District and the Workhouse of the Leek Union.
FOSTER, G. H., M.B., appointed Medical Officer to the Workhouse, Hitchin Union, *vice* O. Foster, M.R.C.S., resigned.
FURLEY, Robert C., L.R.C.P.Ed., appointed Medical Officer to the Poor House at Craiglockhart, Edinburgh.
GALLWEY, John H. M., M.D., appointed Medical Officer and Public Vaccinator for the Ponteland District, and Medical Officer for the Workhouse of the Castle Ward Union, Northumberland.
IRWIN, William, L.R.C.P.Ed., appointed Medical Officer and Public Vaccinator for the Manorcunningham District of the Letterkenney Union, co. Donegal, *vice* J. Smyth, M.D., deceased.
TURTLE, James, M.R.C.S.Eng., appointed Medical Officer for No. 2 District of the Hackney Union.
WALSHE, Denis, L.K.Q.C.P.I., appointed Medical Officer to the Poplar and Stepney Sick Asylum.
WANKLYN, Arthur, M.B., appointed Medical Officer and Public Vaccinator to the Endon District of the Leek Union.
WEBSTER, Henry W., L.R.C.P.Ed., appointed Resident Medical Officer of the Woolwich Union Workhouse and Infirmary.

NEMO.—The primary duty of a Registrar of Deaths is to register every death that occurs within his subdistrict, and to obtain the best information relating to all the particulars thereof required for insertion in the register. With regard to the cause of death, the new Registration Act, in Section 20, says—"In case of the death of any person who has been attended during his last illness by a registered medical practitioner, that practitioner shall sign, and give to some person required by this Act to give information concerning the death, a certificate, stating to the best of his knowledge and belief, the cause of death; and the cause of death, as stated in that certificate, shall be entered in the register, together with the name of the certifying medical practitioner." If all persons were attended in their last illness by registered medical practitioners, the provisions of the new Act would make the certification of the causes of death all but complete. It is well known, however, that many persons are attended in their last illness by duly qualified, although *unregistered*, practitioners; others by unqualified practitioners, and in a certain small proportion of deaths there is no medical attendance whatever during the last illness, and yet all these deaths must be registered. In either of the two first cases it is the registrar's duty, on the production of what purports to be a certificate of the cause of death, to enter such cause in the register, but without the word "certificate", or the name of the practitioner. In cases of deaths, where there has been no medical attendance upon the deceased person, the registrar is instructed to obtain the best information as to the cause of death which the informant can furnish, and of course to omit the word "certificate" from the Cause of Death column in the register.

MILITARY AND NAVAL MEDICAL SERVICES.

MOVEMENTS OF ARMY MEDICAL OFFICERS.—Deputy Surgeon-General J. McGrigor Grant, M.D., is appointed to be principal medical officer at Bermuda, *vice* Deputy Surgeon-General Webb, whose tour of foreign service is about to expire.—Surgeon B. R. Jaggie, M.D., is placed on general duty, Mhow circle, accompanying the draft of 180th Foot to Nusseerabad. Surgeons J. Prendergast and J. E. V. Foss, M.D., are placed on general duty, Poonah circle. Surgeon J. S. Wilkins is placed on general duty, Poonah; and Surgeon W. A. Harren, on general duty, northern division, from December 4, 1874.—Surgeons G. H. Harvey and G. Hare have been struck off the strength of the Aldershot Division. Surgeon W. B. Steele has been ordered to do duty with the 1st Station Hospital at Aldershot.

THE SOURCE OF DISCONTENT IN THE ARMY.

THE *Army and Navy Gazette* contains the following remarks on the discontent prevailing in the Army Medical Department, and its causes.

"The members of the Army Medical Department express fears lest, in considering the cause of the existing discontent, the Secretary of State for War should fail to appreciate the many advantages of the system they one and all so strenuously uphold. To a civilian, the evils of the General Hospital arrangement may not be so apparent as to a soldier. It has, however, to be remarked that it is not juniors alone who condemn the system inaugurated by the warrant of 1873. We happen to know for a fact that, taking the whole list of surgeons-general and deputy surgeons-general, containing forty-three names, there are not half-a-dozen officers to be found who would come forward as supporters of the document in question. When these placed beyond the operations of the objectionable clauses number themselves among its strongest opponents, it must be allowed that things need to be mended. A deputy surgeon-general, writing to us, says:—There is

no fear whatever that a change will not be effected. The complaints are so general, that the staunchest adherent of the late administration would think twice ere he voted in antagonism to a whole department.' The doctors, it is to be hoped, may take heart when we assure them that, two years ago, the writer 'of the above' was one of the greatest believers in the advantages which it was thought would accrue from the alteration. Now he is the very first to raise his voice against the change."

We are not aware of the source whence our contemporary has obtained his information regarding the all but universal concurrence of opinion existing among the administrative officers of the Army Medical Department as to any one particular system of conducting the hospital arrangements. The correspondence which reaches us, and the pamphlets and articles which are published from time to time on the subject, lead us to the conclusion, that there are many conflicting views among them on the topic in question. Certainly not a few medical officers, both administrative and executive, hold strong objections to the application of the regimental system, as it formerly existed, to the circumstances of the present day; while some who have been advocates of the regimental system still desire that the system of hospital administration introduced in 1863, with some modifications, may have a fair trial, which it certainly has not as yet had. There are many combatant officers who do not approve of Mr. Cardwell's system of localisation of the Forces in Great Britain and Ireland; yet, now that it has been introduced, and that much expense has been gone to in providing the necessary accommodation for the troops and establishments connected with the system, they quite admit the necessity of giving it a complete trial. The arrangement of station hospitals is intimately connected with the general plan of army arrangements introduced by Mr. Cardwell, and cannot be got rid of altogether without a change of the whole system. But the general hospital arrangements may be modified in details, and in this way some sources of discontent among individuals may be removed; indeed, it has already been modified in one important particular; viz., that of surgeons attached to regiments attending to the sick soldiers of the particular regiments to which they are attached, and to them only, in the station-hospitals. But there are more important sources of discontent in the Medical Department at large than this or that method of hospital management, and to these we have called attention in several recent numbers of the JOURNAL. Among them, the want of greater professional weight and authority, a more speedy course of promotion, higher rates of remuneration, and of better rates for retirement, hold the foremost place in the minds of most of the army medical officers; and we trust that, when considering the causes of the existing discontent, the Secretary of State for War may have these desiderata, which are of solid importance, prominently brought to his notice by those whose duty it is to call his attention to the subject.

OBITUARY.

ROBERT ADAMS, M.D.T.C.D., F.R.C.S.I.

SURGEON IN ORDINARY TO THE QUEEN IN IRELAND, ETC.

DR. ROBERT ADAMS died in Dublin, on Wednesday, January 13th, at the advanced age of 83. While yet at an early age, he gave promise of great capacity for the art of surgery, and, on the completion of his collegiate studies, entered ardently into the science of comparative anatomy. He then visited the Continent, and made himself practically cognisant with the best methods of performing the most difficult operations; and, on assuming practice as an operative surgeon, speedily gained a high position in the profession. He was a distinguished graduate of the University of Dublin, and held the Regius Professorship of Surgery in that institution. On three several occasions he acted as President of the Royal College of Surgeons in Ireland; he was also a member of the Council of that body, ex-President of the Dublin Pathological Society, surgeon in ordinary to the Queen, and consulting surgeon to the Rotundo, Sir Patrick Dun's, and the Richmond Hospitals. He contributed several articles, on Abnormal Joints, to Todd's *Cyclopaedia of Anatomy and Physiology*, and was the author of the well-known and most valuable work on *Chronic Rheumatic Arthritis*, with an atlas of plates. Although attacked with heart disease, he had a most extensive practice, and may be said to have died in harness, working as he did to a very short period before his death. His remains were interred on last Tuesday, and the funeral was followed by the leading physicians and surgeons of the city in which he resided for so many years.

EDWARD CUTLER, F.R.C.S.

THIS eminent surgeon died on Monday, September 7th, at the residence (15, New Burlington Street), where he had resided and practised since 1842. He commenced his surgical education by becoming a pupil of St. George's Hospital in 1820, when the late Sir Benjamin Brodie was one of the surgeons; and he numbered among his fellow-students Mr. Caesar Hawkins (his junior by a few years), the late Dr. Robert Ferguson, and Sir Charles Locock. He was a successful and popular surgeon of the Lock Hospital for some years. In 1834, he was elected assistant-surgeon of St. George's. His ability, especially as an operator, attracted the notice of Sir Benjamin Brodie, who selected him for his assistant in private practice, and these relations formed the basis of a firm and lasting friendship between them. On the death of Mr. Walker, in 1843, Mr. Cutler succeeded to the surgeoncy of St. George's, and established a reputation there for his eminent success in operations, and in the after treatment of his patients—qualities which soon secured him a large private practice. He became a fellow of the Royal College of Surgeons in 1843, and subsequently obtained a seat in the Council. The patient interest which he bestowed on the cases under his care, united to his bright social qualities, formed a combination which will live in the memory of a large circle of private as well as professional friends. He died at the age of 77, of natural decay, having continued his practice till within two years of his death. He married, in 1824, the daughter of the late Sir Thomas Plumer, Master of the Rolls.

UNIVERSITY INTELLIGENCE.

UNIVERSITY OF CAMBRIDGE.

SCHOLARSHIPS IN DOWNING COLLEGE.—An examination for three minor scholarships will be held in Downing College on Tuesday, the 6th of April next, and the three following days, and will begin at 9 A.M. on Tuesday. The examination will be in classics, elementary mathematics, law, and natural sciences. There will be two papers in law; one on jurisprudence and elementary Roman law, and one on international law; including the relations of these to moral science. The examination in natural sciences will include chemistry, theoretical and practical, physics, comparative anatomy, and physiology. Candidates in law and natural sciences will be expected to show such a knowledge of classics and mathematics as will enable them to pass the previous examination. Persons who have not been entered at any College in the University, or who have not resided one entire term in any such College, are eligible to these minor scholarships, which will be of the value of £60 *per annum*, and tenable for two years, or until their holders are elected to foundation scholarships. No one elected minor scholar will receive any emoluments until he has commenced residence as a student of the College. Satisfactory testimonials as to their moral character must be sent to the Master by all candidates on or before Thursday, the 1st of April, and each candidate is requested to state in which subject he desires to be examined. Further information will, if required, be given by John Perkins, Esq., Tutor of the College.

MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following gentleman was admitted a Fellow on January 28th, 1875.

Hunter, William Guyer, M.D. Aberdeen, India

Admitted Members.

Corbould, Francis John, M.D. Aberdeen, Reigate

Coupland, Sidney, M.D. Lond., Fisham Road

Dukes, Clement, M.B. Lond., Rugby

Elliott, George Frederick, M.D. Dubl., Hull

Evershed, Arthur, Belle Vue

Gowers, William Richard, M.D. Lond., Queen Anne Street

Hunt, Benjamin, M.D. St. Andrew's, Edgbaston, Birmingham

Mackey, Edward, M.D. Lond., Birmingham

Stretton, William Harris, M.D. St. Andrew's, St. Bartholomew's Hospital

Admitted Licentiate.

Edwards, Roger, University College Hospital

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at a meeting of the Court of Examiners, on January 28th.

Manceo Martinho Gonsalves, I.S.A., Cambridge Terrace, Hyde Park; Roger Edwards, I.R.C.I. Lond., Dolgelly, North Wales; Herbert Smalley, Grays, Essex; Francis H. Champneys, B.A. Oxon., Lichfield; Robert Wharry, Charlton, Kent; Edward P. Falshaw, Payswater; John B. Footner, Romsey, Hants; Thomas Smailes, Pickering, Yorkshire; Frederick Henry Spooner,

Plymouth; William V. Harvey, Rutland Street; Awdry Peck, Bath; H. Gordon Cumming, Exeter; Henry A. Lovett, Norwich; George Hastings, Brixton; Wm. R. Basham, Aldershot; and George Hart, Birmingham.

The following gentlemen were admitted members on January 29th.

Messrs. Bernard Pitts, B.A. Cantab., Northampton; Henry North, Winchester; J. Arthur Kempe, Exeter; W. Tonge-Smith, Jamaica; and Levi C. Lane, M.D. Jeff. Coll. Philad., San Francisco, California.

Of the 110 candidates examined, 65 obtained the diploma, and 29 were referred; eight passed in surgery, and when qualified in medicine, will be admitted members of the College; the others, who went in only for surgery, were referred.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, January 28th, 1875.

Parrow, Arthur Haynes, Denbigh Place, Pimlico
Bowker, Edward Harwood, Chesterfield, Derbyshire
Gonsalves, Manoel Martinho, St. Mary's Hospital
Laey, Alexander Gairdner, Guernsey

The following gentleman also on the same day passed his primary professional examination.

Neylan, John, London Hospital

At the Preliminary Examination in Arts, held at the Hall of the Society, on January 29th and 30th, 1875, 51 candidates presented themselves; of whom 26 were rejected, one retired, and the following 24 passed, and received certificates of proficiency in general education. In the First Class, in order of merit:

1. Charles Matthias Lamb. 2. Annie de la Cherois. 3. Henry Hinds Austen.
4. Knowlson Townscand. 5. Charles Graham Havell.

In the Second Class, in alphabetical order:

H. K. Bamber, Joha Cock, J. C. Culling, W. H. Day, T. Dutton, C. H. Fowler, G. C. Hamilton, H. Hawksworth, Joseph King, R. J. Oswald, H. R. Powell, G. W. Roberts, G. S. Robinson, F. H. Saunders, E. W. Shepard, John Smith, H. Tause, Jane Waterson, and A. G. Whitmore.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.—At examination meetings of the College, held on Tuesday, Wednesday, and Thursday, January 12th, 13th, and 14th, 1875, the License to Practise Medicine was granted to—

Kennedy, John William Tully, Edmond
Rae, William Masters

The License to Practise Midwifery was granted to—

Keonedy, John William Rae, William Masters
Murphy, George Wyndham

MEDICAL VACANCIES.

The following vacancies are announced:—

ABBEYLEIX UNION—Apothecary.

ARMY MEDICAL DEPARTMENT—Surgeons. Applications to be made to the Director-General of the Army Medical Department.

ASHTON-UNDER-LYNE UNION—Medical Officer for No. 3 District.

BARONY PAROCHIAL HOSPITAL, Barnhill, Glasgow—Dispenser.

BECKETT HOSPITAL AND DISPENSARY, Barnsley—House-Surgeon.

Salary, £140 per annum, with furnished rooms, gas, and coals.

DERBYSHIRE GENERAL INFIRMARY—Assistant House-Surgeon. Board,

lodging, and washing, but no salary. Applications to Secretary.

DOWNHAM UNION—Medical Officer for No. 6 District.

EMSORTH—Certifying Factory Surgeon.

ESSEX LUNATIC ASYLUM—Second Assistant Medical Officer and Dispenser.

Salary, £100 per annum, with board, lodging, and washing.

FLAX MILLS FRIENDLY SOCIETY—Medical Officer. Salary, £110 per annum.

Applications to A. M. Keeman, 7, Hunston Square, Johnstone, N.B.

GRANTHAM UNION—Medical Officer for the Ropsley District. Salary,

£26:10 per annum.

HARDINGSTONE UNION—Medical Officer for the Brafield District. Salary,

£45 per annum.

HARRIS, Parochial Board of—Surgeon. Salary, £66 per annum, including vaccination and medicine for the poor. The gentleman elected will get £90 per annum for attending the ratepayers and cotars within South Harris. Applications to be made to the Chairman of the Parochial Board of Harris.

HEADINGTON UNION—Medical Officer for the Wheatley District. Salary,

£70 per annum.

HENDON UNION—Medical Officer for the Willesden District. Salary, £40

per annum.

INDIAN MEDICAL SERVICE—Twenty appointments as Surgeon. Examination in February 1875.

KENT AND CANTERBURY HOSPITAL—Dispenser and Assistant House-Surgeon. Salary, £50 per annum, with board and lodging. Applications to be sent in on or before the 12th instant.

KILBURN DISPENSARY—Assistant Resident Medical Officer. Salary, £80

per annum, with apartments.

KILLALA UNION—Medical Officer for the Workhouse, and the Killala Dispensary District. Salary, £50 and £110 per annum, respectively, and fees. Applications to be made on or before the 20th instant.

LEEK UNION—Medical Officer for the Endon District. Salary, £20 per annum.

LICHFIELD UNION—Medical Officer for the Alrevas District. Salary, £35

per annum.

MORVEN, Parish of, Argyllshire—Medical Officer. Salary, £100 per annum.

Applications to H. A. Fraser, Morven, N.B.

NORTH WALES COUNTIES LUNATIC ASYLUM—Assistant Medical Officer.

Salary, £100 per annum, with board, washing, and lodging. Applications to be made on or before February 17th.

PAISLEY INFIRMARY—House-Surgeon. Salary, £80 per annum, with board and lodging. Apply to W. Hodge, Writer, Paisley, on or before February 6th.

REDDITCH AND DISTRICT MEDICAL ASSOCIATION—Medical Officer.

Salary, £150 per annum, with fees and unfurnished house.

ROYAL FREE HOSPITAL, Gray's Inn Road—Two Junior House-Surgeons.

Applications on or before the 10th instant.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City Road—Physician.

Applications to be made on or before February 15th.

ROYAL INFIRMARY FOR WOMEN AND CHILDREN, Waterloo Bridge

Road—Physician.

SAFFRON WALDEN UNION—Medical Officer for the Seventh District.

Salary, £86 per annum.

ST. LUKE'S HOSPITAL FOR LUNATICS—Second Clinical Assistant. Board

and furnished apartments.

SALOP INFIRMARY—Assistant House-Surgeon.

SEAMEN'S HOSPITAL—House-Physician. Salary, £120 per annum, with

furnished rooms and attendance. Applications on or before the 22nd instant.

SMALLBURGH UNION—Medical Officer for the Ludham District. Salary,

£52:14 per annum.

THINGOE UNION—Medical Officer for the Seventh District.

TYNEMOUTH UNION—Vaccination Officer.

ULVERSTONE UNION—Medical Officer for the Hawkshead District. Salary,

£20 per annum.

UNIVERSITY COLLEGE HOSPITAL—Resident Medical Officer. Applica-

tions not later than February 12th.

UNIVERSITY OF EDINBURGH—Additional Examiner in Medicine.

WEST WARD UNION—Medical Officer for the Patterdale District.

WISBECH UNION—Medical Officer for the Third District. Salary, £30

per annum.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

FLEMING, William J., M.B., appointed Assistant to the Professor of Physiology in the University of Glasgow.

GOODHART, J. F., M.D., appointed Physician to out-patients, Evelina Hospital

for Sick Children, *vice* F. Taylor, M.D., appointed to the in-patients

HOLLIS, E. M.B., appointed Resident Medical Officer to Chalmers' Hospital,

Edinburgh, *vice* A. R. Coldstream, M.B., deceased.

HUMPHREYS, Henry, M.R.C.S.Eng., appointed Medical Registrar at the Middle-

sex Hospital, *vice* S. Coupland, M.B., resigned.

LAMB, William H., M.R.C.S.Eng., appointed House-Surgeon to the Sheffield

Public Hospital, *vice* G. E. K. Thorpe, M.R.C.S.Eng.

***LEVINGE**, E. G., A.B., M.B., appointed Junior Assistant Medical Officer of the

Hants County Lunatic Asylum, Knowle, Fareham.

LYELL, Robert W., M.D., appointed Surgical Registrar at the Middlesex Hos-

pital, *vice* A. Clark, F.R.C.S.Eng., resigned.

MEIGHAM, Thomas S., M.D., appointed Surgeon to the Glasgow Eye Infirmary.

MUNRO, Aeneas, M.D., C.M.Univ. Edin., F.F.P.S.Glas., appointed Assistant-

Physician to the Hospital for Women, Soho Square.

POWELL, Evan, M.R.C.S.Eng., appointed Assistant Medical Officer to the Essex

Lunatic Asylum, *vice* R. L. Shone, M.R.C.S.Eng., resigned.

REEVES, Henry Albert, M.R.C.S.Eng., F.R.C.S.Eng., appointed Surgeon to the

Hospital for Women, Soho Square.

SMITH, Roland D., M.R.C.S.E., appointed Junior Resident Medical Officer to the

London Hospital, *vice* H. T. Shapley, M.R.C.S.

TAYLOR, Frederick, M.D., appointed Physician to the in-patients, Evelina Hos-

pital for Sick Children, *vice* C. Hilton Fagge, M.D., resigned.

THOMPSON, H. G., L.K.Q.C.P.I., appointed Resident Medical Officer to the

Western Dispensary, Westminster.

THORPE, G. E. K., M.R.C.S.Eng., appointed Surgeon to the Sheffield Public Hos-

pital.

WADDELL, John C., M.D., appointed Assistant-Surgeon to the Norwich Lying-in

Charity.

WADDY, Henry E., M.R.C.S.Eng., appointed Surgeon to the Gloucester Infirmary,

vice J. P. Wilton, M.R.C.S.Eng., resigned.

WILTON, J. P., M.R.C.S.Eng., appointed Consulting Surgeon to the Gloucester

Infirmary.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.

BIRTHS.

ELLIS.—On January 21st, at Reynoldston, near Swansea, the wife of Henry Vause Ellis, M.B., of a son.

IMAGE.—On February 2nd, at Westgate Street, Bury St. Edmunds, the wife of Francis E. Image, M.B. Cantab., of a daughter.

DEATHS.

ARCHER.—On January 28th, aged 62, Maria Elizabeth, wife of George Esq., Surgeon, Feltwell Brandon.

KEELE, Henry W., M.D., Staff-Surgeon R.N., at Highfield Lodge, near Southampton, aged 84, on January 23rd.

KEVIN, Charles, Esq., Deputy Inspector-General of Hospitals, late of the Madras Medical Establishment, aged 67, at Oxford Terrace, on January 24th.

MARTLAND.—On January 28th, Maggie, the wife of William Martland, M.R.C.S.Eng., St. John's Lodge, Blackburn, aged 34. Friends will please accept this intimation.

DR. CHARLES T. VACHELL.—At the annual meeting of the governors of the Glamorganshire and Monmouthshire Infirmary, the following resolution was passed:—"That the warmest thanks of the governors are due, and are now offered, to Dr. C. T. Vachell for his attention to the duties of his office, and especially for his kindness while house-surgeon to the patients under his charge; and this meeting desires to record its regret at losing Dr. Vachell's services."

OPERATION DAYS AT THE HOSPITALS.

MONDAY	Metropolitan Free, 2 P.M.—St. Mark's, 6 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.
TUESDAY	Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.
WEDNESDAY	St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 1 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.
THURSDAY	St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.
FRIDAY	Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.
SATURDAY	St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M.—Royal Free, 9 A.M. and 2 P.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY	Medical Society of London, 8.30 P.M. Mr. T. S. Dowse, "Some Practical Hints on the Relief of Pain by the External Use of Hydrate of Chloral"; Dr. Sinsom, "A Case of Presbyopia Murmur (patient shown)"; Dr. Thudichum, "On Chemical Statics of the Brain"; Royal College of Surgeons, 4 P.M. Mr. Erasmus Wilson, "On Dermatology".
WEDNESDAY	Epidemiological Society, 8 P.M. Dr. Squire, "Further Remarks on the Period of Infection in Epidemic Disease"; Royal College of Surgeons, 4 P.M. Mr. Erasmus Wilson, "On Dermatology".
FRIDAY	Clinical Society of London, 8.30 P.M. Dr. Vivian Poore will exhibit a patient with Paralysis of Serratus Magnus; Dr. Southey will exhibit a patient with Lepa Anæstheticæ; Mr. Pugin Thornton, "Notes of a Case of Exceeding Infrequency of the Pulse"; Dr. T. F. Whipple, "Notes of a Case of Fatal Pleuropneumonia in an Opium-eater"; Royal College of Surgeons, 4 P.M. Mr. Erasmus Wilson, "On Dermatology".

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS NOT ANSWERED, are requested to look to the Notices to Correspondents of the following week.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with *Duplicate Copies*.

AUTHORS desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

FOREIGN DEGREE.

SIR,—In my letter to your JOURNAL a few weeks ago about foreign degrees, I gave some information concerning the M.D. of Brussels and Giessen. A short time ago, I wrote to the Dean of the Medical Faculty of the University of Giessen, asking information about their degrees, more especially those of medicine. In reply, I had a letter, in excellent English, stating that the fee for the M.D. was £20; that the candidate could be examined in English, and that the examinations lasted about three hours. The letter was signed, I think, "Dr. Eschardt". I have, unfortunately, mislaid it, and so cannot be positive. I will be obliged if M.D. Giessen will give in your JOURNAL some information, for those who intend visiting Giessen, as to the route, the nature of the examination, and best hotel accommodation. If he would also kindly answer me some further questions, I will be glad if he will forward me his address, under cover, to your office.—Yours truly,
January 12th, 1875. A PHYSICIAN.

MR. BRACK MARSHALL.—In refusing to make up the lotion, Mr. Goodwin was clearly wrong, and his observations were unmitigated. In refusing to supply strychnia for the dog, except under the conditions of the Poisons Act, Mr. Goodwin was clearly right. The first was a prescription; the second was not.

PUERPERAL FEVER.

SIR,—In answer to Obstetricians, I beg to state that during puerperal fever at Doncaster, many years ago, Mr. Storr had to burn all the clothes he had worn, and to absent himself from Doncaster, I think, three weeks, before resuming his practice of midwifery.—I am, etc.,
W. A. S.

ALPHA.—The solution of most morphia-salts darkens in colour by keeping; this is due to a slight decomposition. The hypodermic solution of acetate of morphia has been kept for months, and although it has become much darker, there has not been any perceptible diminution of strength.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

ON THE INFLUENCE OF TEMPERATURE DURING CHILD-BIRTH.

SIR,—In the regulation of the temperature of the body lies the key to the problem of the successful management of natural labour, and of the condition subsequent to it. For the safe conduct of labour, it is essential that the mind be calm, and the body warm and perspiring; and everything which conduces to these results conduces equally to the well-being of the patient and to the progress of labour. Of the correlation of the mind and body and of the body's temperature, it is impossible in this letter to allude except in the briefest manner. Nowhere is this interdependence so emphatically expressed as during childbirth. Then, as every practitioner is aware, the slightest feeling of apprehension is sufficient to arrest in a moment the whole progress of labour. In a moment the colour leaves the face, and the temperature of the body is, for a time at least, reduced.

"In calmness and confidence shall be thy strength." This excellent motto, beautifully illuminated in gold and colours, should, I venture to suggest, be suspended in a conspicuous position in the chamber of every woman about to become a mother, and should be the subject of frequent reflection. Of the significance of a warm climate in affording its proverbial facility to childbirth, it may be sufficient to remark that the condition of body which there occurs naturally should, in a colder climate, be induced artificially; and the first thing which in general is instinctively done is to light a fire. Under the influence of a great and general activity of body, aided and sustained by an elevated surrounding temperature, labours, even in this country, are sometimes begun and ended with surprising rapidity. A person who was occupied in baking cakes, whilst standing before a large bread-oven, was suddenly taken with her first and only pain, and had barely time to kneel down in front of a chair before the child was born. This I regard as a typical case; and it is worthy of consideration whether precisely similar results might not, as a rule, be accomplished were the mass of parturient women subjected to equally favourable conditions.—I am, etc.,
H. Harlesden, January, 1874. M.D.

MR. PARTRIDGE (Stroud).—The name of the person issuing the circular is not—as far as we can find—in the *Medical Register* or in the *Medical Directory*; and it appears not to be M.D. of any British University. Inquiry of the authorities of the University of Edinburgh and of the Medico-Chirurgical Society of Aberdeen might ascertain with what justice he parades the names of these institutions in connection with his own.

DENTAL SURGEONS.

At the written examination for the license in dental surgery of the Royal College of Surgeons on January 8th, the following questions on anatomy and physiology, and pathology and surgery were submitted to the candidates. The candidates were required to answer at least one of the two questions both on anatomy and physiology and on pathology and surgery.—*Anatomy and Physiology*: 1. Describe the attachments of the buccinator muscle, how it is engaged in mastication, and whence it derives its vascular and nervous supply. 2. From what source is the fluid in the mouth derived? State the principal causes which influence the amount formed, and explain how those causes act.—*Pathology and Surgery*: 1. Describe the origin and development of a cyst in the lower jaw. How would you distinguish it from other tumours in this region? and what does it usually contain? and state how you would treat it. 2. Describe the treatment you would adopt in continued hæmorrhage after excision of a portion of a tonsil.—In dental anatomy and physiology, and in dental surgery and pathology, candidates were required to answer at least two out of the three questions on each subject.—*Dental Anatomy and Physiology*: 1. Explain fully the different theories concerning the formation of dentine, especially in relation to the tubuli. Of what do their contents consist? and how may they be pathologically affected by disease? 2. State the ages at which the eruptions of the deciduous and permanent sets of teeth commence, and the ages at which they are respectively completed. Describe the characters by which you would distinguish between the first and second molars of the deciduous set, and between the first and second lower molars of the permanent set. 3. Explain the several circumstances which conduce to the protrusion of the chin and the shortening of the face in old people; and describe the ways in which artificial teeth rectify such conditions.—*Dental Surgery and Pathology*: 1. Draw a distinction between toothache arising from diseased conditions of the teeth and pain in teeth arising from constitutional causes. Name the constitutional conditions and diseases which principally affect the teeth. 2. Describe the conditions under which certain of the permanent teeth in the adult may be wanting from the mouth when none have been extracted. Point out the particular teeth most frequently absent, and state the circumstances which probably explain such deficiencies. 3. What are the different varieties of united teeth, and the nature of the union? State the probable causes of such union between contiguous teeth, and the consequences to which that condition may lead.

NEMO.—There was an examination for the "L.M." on Thursday week. We believe it is eighteen months since the last took place, and in all probability will be much longer before the next occurs.

POISONING BY NITRIC OXIDE.

SIR.—Unfortunately, the printer has given the wrong title to my query: the error may, of course, be due to my very bad writing. What I wanted to learn was, the best and readiest mode of counteracting the effects produced by inhaling nitric oxide fumes, not nitrous oxide. How to act in cases of poisoning by the latter gas is, I hope, well known to all the members of our profession.—I am, etc.,
January 30th, 1875. M.R.C.S.E.

MR. BENJAMIN BLOWER.—Your letter is inadmissible, as it wholly departs from hygienic considerations, to enter into a discussion on theological matters, the importance of which we do not undervalue, though we consider that they would be out of place in these columns.

"OS SACRUM" (St. Bartholomew's).—You will find the following lines in Butler's *Hudibras*.

"The learned Rabbins of the Jews
Write there's a bone, which they call 'Luz',
The rump of man, of such a virtue,
No force in Nature can do hurt to;
From whence the learned sons of Art
'Os Sacrum' justly call the part."

NOTICE TO ADVERTISERS.—Advertisements for insertion in the *BRITISH MEDICAL JOURNAL*, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than *Thursday*, twelve o'clock.

THE FEVER AT LEWES.

SIR,—In your notice of the outbreak of enteric fever at Lewes, in page 155, it is stated that "the disease having been evidently due to defects connected with the system of water-closets, we are not surprised to hear that an effort is about to be made to induce the population to abandon this means of removal of excrement." I sincerely trust that efforts to induce them to do so will utterly fail, for the natural course to follow the discovery of defects in a system which has elsewhere proved eminently successful, is not to abandon the system, but to remove its defects. It is not stated what the special defects are, but most probably they are such as allow of the escape of air from the soil-pipes into the dwellings. At Croydon, many years ago, an outbreak of fever, as well as its continuance in less violent form, was with great probability attributed to this cause; but since the soil-pipes have been continued to the tops of the dwellings, and means of free escape of sewer-air provided, Croydon has been remarkably free from enteric fever; and it is all but certain that if this very simple remedy were adopted at Lewes, it would be followed by the like complete success.

It may probably be contended that the same result will follow the substitution of earth-closets for the present system; but that is far from probable, as a permanent result, though it possibly may be so during the continuance of a carefully conducted experiment. I have known several instances of different modes of disinfection, apparently very successful as long as they were carefully watched, fail utterly when that vigilant watchfulness became relaxed. No doubt pigs might be kept in a town without creating any nuisance, if every one who kept them were as careful in preserving the extreme cleanliness that in some rare instances I have known to be observed; yet few would be silly enough to propose that, by keeping of pigs in towns should be encouraged, because it would be possible, by enforcing extreme cleanliness of pig-sties, to prevent them from being nuisances; for every one knows that this, though physically easy, would be usually nearly impossible. But such a proposition would not be much more foolish than that of encouraging the inhabitants of a town to form collections of compost, consisting of human filth, covered with a sprinkling of earth, in close contact with every dwelling, on the bare chance that every one of such collections will always be so carefully managed as not to be a nuisance, thus rendering the safety of every one dependent upon the carefulness of every one living near. It will, no doubt, be urged that all that is needed is a little constant care. Exactly so, but that is just what is most difficult to secure. Surely we have had experience enough to prove this. Amongst the minor miseries of life, one of the most common is the difficulty of getting our dust regularly taken away. I know many who, like me, have failed, but never heard of one who succeeded in having this needful work even tolerably well done.* What right have we to expect that earth-closets will be better attended to, and will not be as our dust-holes are, constant causes of vexation, annoyance, and danger? Where there are no sewers and no regular water-supply, and where land under cultivation is close at hand, an earth-closet is a convenient arrangement; but to introduce them in towns where water-closets can be used, because those are dangerous when easily avoided defects are permitted to continue, would be a backward step indeed.—I am, etc., P. H. HOLLAND.

*The defect with which the outbreak of fever at Lewes was associated, and which has been described in a previous number of the *JOURNAL*, was not that which Mr. Holland supposes, but one which led to contamination of the town-water; and though it has been completely remedied, we were not surprised, considering the magnitude of the evil in which it had resulted, to hear that the opportunity had been made use of by those who are desirous of introducing a different system of excrement removal. If all that Mr. Holland alleges against the dry-earth system turn out to be true, it is certainly inapplicable to towns; but it is precisely experience of this sort which is required. The system has answered well in public institutions, and we shall be glad to know from the Lewes experiment whether or not it can be applied to towns.

MR. J. H. WATSEN and a Liverpool Associate write to express their satisfaction at the resolution of the Committee of Council relating to the "Norwich prosecution".

FUNGUS OF THE EXTERNAL EAR.

SIR,—Will you permit me to ask that your correspondent "D. McD.", who reports his own case of ear-disease, supposed to be caused by a fungus in the meatus, may be good enough to send a specimen of the parasite to me for examination? As I am rather interested at present in this form of ear-disease, may I be permitted here to state that I shall esteem it a favour if any of my professional brethren, having similar specimens in their possession or cases under their care from which they may remove fungus-like debris, to send such to me for inspection, together with a concise history of the case from which the fungus was removed. I shall gladly defray any expense connected therewith, and return the specimens, if desired to do so. The object I have in making this request is this: I have been for some time on the look-out for one or other of the rarer varieties of fungus, said to have been found by Steudener, Hassenstein, and others, till now without success. I have reasons (probably not well founded) to believe that I shall not find them; but if the request I now make is responded to freely (I have already shown that disease of the ear due to fungus is not at all rare in this country), I may succeed in finding the object of my search.

In conclusion, I may state, *à propos* of your correspondent's remarks as to the relative values of lamb's and cotton-wool, that in my experience neither variety produces "irritation". Properly applied—as, for instance, in the relapsing form of *otitis furunculosa*, or (*à la* Vearsley) to increase the labyrinthine pressure—it is in many cases invaluable. With these exceptions, however, its use in the course of disease of the ear is only temporary, as a protective after operations or in acute diseases. In chronic cases, its use, for obvious reasons, is inadmissible.—I am, sir, your obedient servant, JAMES PATTERSON CASSELLS.

2, Newton Terrace, Glasgow, January 11th, 1875.

CHIRURGUS.—The French medical paper which gives most attention to surgical work is, we think, the *Gazette des Hôpitaux*. The annual subscription in Paris is thirty francs. The offices are at 5, Rue des Saints-Pères. The cost of postage to England is charged in addition.

*At a recent meeting of the Chelsea Vestry, 587 complaints were reported, all relating to the non-removal of dust. (*News of the World*, January 24th, 1875.)

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the *BRITISH MEDICAL JOURNAL*, should arrive at the Office not later than 10 A.M. on Thursday.

PRESCRIBING FOR THE MILLION.

SIR,—I observe in a daily paper a report of a "Gresham Lecture", by Dr. Symes Thompson, On Catching Cold, in which occurs the following paragraph. "Mixed with hot water and nutmeg, spirits—rum especially—had great power of promoting perspiration, and therefore of relieving cold. The drugs having an analogous effect were ather, especially when taken in small and repeated doses of two drops to a teaspoonful of water every ten minutes; opium, of which some people took half a teaspoonful on going to bed, and after a heavy sleep woke up with a dry mouth and a tendency to headache, but free from cold." Next day appeared the following correction: "In our report of Dr. Symes Thompson's lecture 'On Catching Cold', reference was made to opium being taken in half-teaspoonful doses. The drug alluded to was tincture of opium." I do not think the correction any great improvement on the error, and I almost doubt whether the Gresham Lectures were intended to be the medium of "prescribing for the million". The Gresham Lectures used to be dignified, able, and serious productions, delivered in Latin. It may be wise to lower them to the million and deliver them in English; but in adopting this form of popular prescribing for common ailments, I doubt whether Dr. Thompson is consulting his own dignity or fulfilling the objects of the endowment.—I am, etc. CIVIS LOND.

MEDICAL DEGREES AND TITLES.

SIR,—M.A. Oxon., whose letter you published in your last issue, seems to esteem his degree much more highly than it deserves. To obtain the degree of B.A. is by no means a difficult matter to a man who has resided at Oxford the necessary time, and who has had the great advantage of being well ground up for the examination; in fact, many men of very inferior abilities obtain it. The M.A. of necessity follows, if the candidate reside the required time; indeed, I believe that residence is not at all necessary, but that any B.A. of three or four years' standing, who has entirely forgotten all he knew when he obtained the degree, has merely to pay the necessary fee to become M.A. The higher degrees of B.D., D.D., etc., are granted, I believe, after much the same fashion; so that I cannot see that M.A. Oxon. has much cause to write a high-sounding letter regarding his University distinctions. But, presuming its degrees to be all he thinks them to be, he must remember that the standard required for University honours differs at each of the Universities in the United Kingdom; and it would seem, therefore, as sensible to deny a B.A. of Aberdeen the right of using the title because he did not obtain it after the same ordeal as at Oxford, as it is to exclude men who have gone through a course of study, and have passed an examination, sufficient to allow human lives to be entrusted to their medical care, the privilege of taking a degree in medicine, if they can pass an examination to obtain it. Again, if in speaking for myself I may speak for others who desire the distinction, to take a degree without a thorough examination is the furthest from our wish; but we want to prove to those who believe us beneath them in medical knowledge, because we have no degree, that, even after several years of hard work in practice, we can pass an examination which would be a sore trial to many who are already M.Ds.

Respecting M.A. being "made straight off", your correspondent seems to think that impossible. Does he never see in the daily papers, that His Grace the Archbishop of Canterbury has, after examination (and not always that), conferred the degree of M.A. on certain gentlemen whose names follow the announcement?

Your correspondent seems to think that those who only possess a license to practise have undergone no education in medicine; he forgets that four years of study are required, three of which must be spent at a medical school. I myself spent nearly seven years in study, five winter and four summer sessions being spent at one of the best medical schools in London, where I obtained distinction in more than one branch of medicine, and attended all the courses required for the M.D. Lond.; and yet, from circumstances over which I had no control, was unable to obtain a degree.

Again proposing that some university be petitioned respecting this matter, I am, Sir, your obedient servant, A COUNTRY PRACTITIONER.

January 25th, 1875.

SIR,—A L.R.C.P. is an apothecary, and has many privileges, some to be envied, others not. A L.R.C.P. is a physician, and reference to a Latin dictionary will explain the meaning of "Doctor". A graduate of an university is M.D. Can there be greater plainness? Why all this not to be commended correspondence because a L.R.C.P., who no doubt twelve years ago was told he should use the courtesy prefix Dr., wishes to distinguish himself from an apothecary, who often brings no credit on the profession by keeping "open shop". The only legal enunciation of what is law pronounces him a physician, and it must therefore follow he is a Dr. I see in this a very proper and laudable distinction, and it robs no one of his right; because a graduate can, if he choose, and wishes it to be known, put his coveted M.D. on his plate, etc.; and the old and valued apothecary, by his plain Mr., will show he prefers it.—Yours, etc., M.D. and L.R.C.P.

SIR,—When looking over your valuable *JOURNAL* of the 2nd instant to-day, my attention was considerably attracted by a letter which appeared therein concerning "Medical Titles" contributed by a L.K.Q.C.P.I. As a student in medicine, I will reply as best I know to L.K.Q.C.P.I.'s "few general questions" (as he terms them) to some of his M.D. adversaries, for the simple reason that I feel satisfied graduates in medicine will not consider it worth their trouble to reply to such absurdities, as I will now prove his queries surely are.

In the first place, he asserts that he is a Doctor legally and morally because he and his brother happen to be Licentiates of a College of Physicians, and he wishes to know "if physicians are not Doctors, what are they?" I say that they are merely physicians, and not Doctors, as I consider, in my humble opinion, that it is quite as absurd to assert that Licentiates in Medicine are Doctors as that Licentiates in Law are Doctors in the same Faculty, or that Licentiates in Divinity are also Doctors, etc. As to the example which he illustrates concerning the prefix "Surgeon", I hold that it is not at all a parallel instance in the present argument. If I could be induced to believe that a Licentiate of a College of Physicians is legally and morally a Doctor, I would no longer trouble myself with the extensive and costly curriculum which the Universities now demand. The learned editor of the *Dublin Medical Press*, when condemning the conduct of a L.K.Q.C.P.I. six months ago, for having signed a medical certificate as a Doctor in Medicine, said that the dignity and honour of the College were being compromised by such proceedings, and that he who obtains the credit of such qualifications without being entitled to them is sailing under false colours; and he concluded by hoping that the Fellows of the College would consult their own dignity rather than en-

courage such disingenuous misrepresentations. L.K.Q.C.P.I. also wants to know in what single way a M.D. man is more a Doctor than a Licentiate of a College of Physicians. I say that it is simply because the former holds a Doctor's degree and the latter does not. He might as well ask in what single way is a L.S.A. more an apothecary than a L.K.Q.C.P.I., both having diplomas to practise medicine. As to the prefix "Engineer", I look upon such an example as having about as much weight in the present argument as I do on that of "Surgeon", which I criticised in a foregoing paragraph. I fully concur with his opinion as to the scouting of examiners for foreign degrees. So I will now take the liberty of informing Mr. Licentiate that he is both a physician and surgeon, but no more a Doctor of Medicine than the writer, who is possessed of neither license nor degree.

All Licentiates know that the M.D. is a mark of higher professional attainments and scholarly culture than the License of a College of Physicians; and I feel satisfied that they knew this as well as I did before they entered a College at all, therefore I am of opinion that they should be content with what qualifications they now hold, or else, without rushing into public print, comply with the bye-laws of some British University, pass the examination, and obtain the degree.

Apologising for trespassing on your valuable space, I am, sir, your obedient servant,
JANUARY 11TH, 1875.

ESCALAPUS.

SIR,—Please allow me a very few words on the vexed subject of "Medical Titles". Nearly all your correspondents seem to leave out of view entirely the commonsense aspect of the question: simply this, that some men would like to rectify an omission of their student days. All of us would like to do the same. I, for instance, regret, and will never cease to regret, that I did not pass the preliminary examination of the London University, because, now that I would wish to appear for the F.R.C.S. Eng., I find that an examination in Greek is required, and I have neither time nor inclination to "get up" Greek again. Still, though a surgeon, I have no more right to dub myself F.R.C.S. than a L.R.C.P. has to dub himself M.D. They ought, and I ought, to have considered these things when a student. When a Licentiate is called Doctor by courtesy of his professional brethren, he ought to remember that the title is given him out of respect to the profession, as it does not redound to our honour to tell the public that So-and-so is not a Doctor. I have noticed that it is only those men who have not the M.D. degree who stickle for the title of "Doctor". Those who have the degree care not what they are called; and if in general practice, like myself, are as often called Mr. as Dr. I do not object to call a L.K.Q.C.P. Doctor, but I object to his signing after his name M.D.—I am, etc.,
M.D., M.R.C.S.
